U. S. v. Robert Friedland

Repository Name: USGS - Spokane
Repository Location: Spokane, Washington
File Bates No. BOMSPOK 0001 through BOMSPOK 0004
File Owner: USGS- Docket No. OME-6344
File Location: Spokane, Washington

Bates #	Date	Document Title (type)	Description	# Pg	Addressee + Addressee's Organization	Author + Author's Organization	CC/BCC	Privilege	Comment
0001	5/22/73	Memorandum (memo)	response to request for legal advice on requirement to pay royalty on certain production from Summitville	6	Chief, OME	C. Brewster Chapman, Jr., DOI Office of the Solicitor.	none	CBI	Privilege asserted for pages 1,2 and 5 only, other pages released; copy of same document in file BOMSPOK 0002

FINAL REPORT
SUMMITVILLE MINES PROJECT
W. S. MOORE COMPANY

Rio Grande Co., Colorado
Docket No. 6344
Amended Contract No. 2189

INTRODUCTION

This report summarizes all exploration work and resulting ore reserves from the above contract. The discussion is limited to geologic descriptions and interpretations, since the summary of work and money spent will be covered in a separate report by V. G. Etem, Resident General Manager of the project.

ANNIE VEIN SUBPROJECT

Seven cuts have exposed the Annie vein system quite well. (See plan map). One vein extends the length of the area in a N 70°W direction, and is probably the "Portal Vein" at the Copper Hill portal, mentioned in early reports on the Summitville Mine. The width is good (8'-10'), but the gold-silver assays were quite low. Similar assays were obtained from a parallel vein 50 feet southwest. Copper assays were also run, and as expected, were very low in the oxide zone. The highest assay (5' .14 Au, 2.46 Ag, .171 Cu) is from a vein on top of Copper Hill Knob. Since this

is only 100' from the Hidden vein, it may be a split from this vein or a separate one within the Annie vein system. However, it is not ore-grade where sampled and does not appear to be a strong vein worth drilling at depth. Stage II of the Annie vein subproject did not appear warranted, and no further work was done.

TEWKSBURY PIPE SUBPROJECT

Results from this project were most encouraging since substantial ore reserves were found, and these will be further described under the ORE RESERVE section. Please refer to the South Tewksbury Area Geologic Map, the Tewksbury long-section, and the drillhole cross-sections for all data.

Hole T-1

In Hole T-1, a substantial oxide ore zone was found from 93'-110'. Average widths and grades are as follows:

Depth	Width	Oz Au	Oz Ag	$/Ton
93'-110'	17'	.25	3.54	$14.91
103'-110'	7'	.35	3.12	17.68

Because of the flat hole angle of -10°, the vein was intersected nearly at right angles and these are true widths. The vein is on the footwall side of the Tewksbury Pipe. Low-grade mineralization is present throughout the first 93 feet of the pipe which

consists of vuggy quartz or completely silicified quartz latite. Quartz-alunite alteration extends for 120 feet into the footwall of the Tewksbury Pipe, but does not appear to contain much disseminated mineralization. The balance of the hole showed moderate alteration of the argillic-chloritic type and weak to moderate pyritization. The vein correlates quite well with the high-grade surface zone sampled by Newmont Mining Company (Average assay is shown on cross-section), and very likely is an extension of the Tewksbury vein into the pipe itself.

Hole T-2

This hole also intersected ore in the Tewksbury Pipe. Widths and grade are substantial, particularly over 15 feet, and a 35-foot lower-grade zone may also be considered as ore. The following averages illustrate the encouraging results.

Depth	Oz Au	Oz Ag	$/Ton
5'-40'	.20	6.80	$18.83
25'-40'	.33	10.9	30.52

Because of the flat angle, widths as given are all true.

The deeper veins at 295'-310' and 322'-329' are probably part of the Parole vein, but Hole T-2 would intersect the vein at a very acute angle, and the results cannot be considered as too reliable.

Hole T-3

Drilling intersected two veins, the T-1 vein near the collar, and the main Tewksbury vein in 3 segments from 130'-188'. Only the hangingwall vein portion of the Tewksbury is of interest, where 5 feet assayed .02 oz Au and 8.81 oz Ag, a gross value of $16.03/Ton. Although this width and grade is presently marginal, it does illustrate the persistence of substantial values to a depth 325 feet below surface and helps confirm the orebody drilled in Holes T-1 and T-2. Vein T-1 was low-grade but does have persistent silver values over 18 feet. The indicated flattening of dip is somewhat exaggerated on the cross-section, since T-3 is 30 feet ahead of the section, and the vein strike of N 30°W is not at right angles to the E-W section.

Hole T-4

The Tewksbury vein was cut from 408'-413', for a true width of 3.5 feet. This was the 4th hole in succession which found ore in the Tewksbury Pipe area. This interval assayed .04 oz Au, 8.9 oz Ag, and 2.93% Cu, or a gross value of $39.54/Ton. The footwall was quite barren, but 5 feet of the hangingwall assayed 1.44 oz Ag and 0.24% Cu. As is typical with the Tewksbury vein, the quartz-alunite alteration envelope extended only 5'-10' into

each wall. This hole is unusually favorable since it extends the ore, found in previous DMEA drilling below the Iowa level, to ore found under this program farther south. Total strike length is at least 500 feet. It also extends the known orebody above the Iowa level to a depth 250 feet below.

Another vein was intersected from 59'-79', and quartz-alunite alteration extended from this vein to surface. None of this zone was of ore-grade, but silver is consistently present at about 1 oz/ton, and the interval 66'-71' assayed .025 oz Au and 1.1 oz Ag. No copper assays were run on this upper vein, which is in the leached oxide zone. Hole T-4 showed the first substantial copper assays as the sulphides, enargite and tennantite, since Holes T-1, T-2, and T-3 were all more oxidized and leached. The rock between the two veins is strongly argillized quartz latite porphyry with considerable chlorite. Another weak vein was found between, which might correlate with the T-1 vein, as found in Holes T-1 and T-3.

Parole Vein

Although this vein was not drilled, surface sampling showed appreciable silver values, and the increased silver prices make this vein more attractive for future exploration. Surface mapping shows a somewhat erratic vein extending for 600 feet along strike.

HIDDEN VEIN SUBPROJECT

All data is shown on the Hidden Vein Long-Section, as no plan map was prepared of the bulldozer cuts.

Hole GH-1

This hole was planned to explore the Hidden vein 200'-250' below the ore-grade outcrop at surface. The projected vein should have been intersected at from 300'-320', but only disseminated pyrite was found, and the hole was continued to 360 feet. A strong fault with pyrite mineralization was cut at 340'-343', which is believed to represent the expression of the vein at this depth. Evidently the Hidden vein does not have the same depth continuity in this area as in the old workings 500 feet north, and it was recommended that Hole GH-2 not be drilled.

Hidden Vein Bulldozer Cuts

Two of the four cuts found vein material along the projected strike of the Hidden vein. Locations and assays are shown on the enclosed long-section. Cut #1 showed quartz-alunite alteration but no vuggy quartz vein. The second cut north of the old prospect shaft on the Hidden vein contained a narrow vein 1.5 feet wide, which assayed .23 oz Au and 7.03 oz Ag. Cut #3, in the drainage north of the Iowa dump, did not find vein material only 70 feet along strike from the outcrop, thereby indicating

an erratic nature to the Hidden vein in this area. An aplite dike was present. Cut #4, between the Iowa boarding house and the Iowa dump, cut a substantial 9-foot vein, but the assays were low.

In view of the erratic nature of the Hidden vein, both from the bulldozer cuts and Hole GH-1, no further work appeared to be warranted and this subproject was discontinued.

DEXTER VEIN SUBPROJECT

Two holes were completed under this subproject, both planned to explore the Dexter vein in the oxide zone below the very substantial outcrop on surface and above where sulphide ore has been found on the Chandler level. (See Dexter vein long-section).

Hole GD-1

This hole intersected the vein near the intersection with the Highland Mary vein. Although the vein was strong, copper values were leached away and gold-silver values were likewise low, as evidenced by the assays on 4.5 feet (.09 oz Au and .05 oz Ag).

Hole GD-3

After Hole GD-3 was completed under the OME contract, the operator has drilled a deeper hole to pierce the Dexter vein well

down in the sulphide copper zone. Both this hole, SD-1, and GD-3 are shown on the same cross-section. Hole GD-3 intersected a wide but weakly mineralized vein from 97'-114', which was the only vein of consequence found. This was believed to be the main Dexter vein until Hole SD-1 was completed, which intersected a wide ore-grade vein directly below this and another directly below the previously known Dexter vein on the Chandler level. Since 10 feet of core was lost in going through the old workings in Hole GD-3, the old working must have been driven on the Dexter vein proper. This new vein to the north was practically unknown except for meager surface evidence. It has been termed the North Dexter vein, and the original one, the South Dexter vein. The grade in Hole SD-1 is remarkably good; 59 feet averages .028 oz Au, 1.23 oz Ag, and 3.89% Cu.

The Dexter adit, directly below, was reopened and sampled at the Operator's expense, with only low-grade values found. The vein width, however, was wider than the drift in most places. These results, combined with those from Holes GD-1 and GD-3, indicate that the oxide zone of the Dexter vein is generally too low-grade to have any possibility for other than very small pods of ore, and no further drilling was justified. The very

substantial copper values found in the sulphide hole, SD-1, 285 feet below, were apparently leached away in the oxide zone.

ESMOND-PICKENS CROSS VEIN SUBPROJECT

A series of cuts were planned to open up the complex of cross veins in the vicinity of the Esmond and Pickens veins. Although the veins continued to the west and the widths were good, the grade was low (See plan map), thereby making further drilling under Stage II inadvisable.

Later rehabilitation by the operator of the North Tewksbury drift afforded a look at these veins at the Reynolds level. The veins were again strong, but low-grade, thereby indicating that extensive reserves are not likely on these cross-veins.

ANNIE VEIN - NORTH EXTENSION

This work was approved by a later amendment to the contract and consisted of drilling to explore a geochemical anomaly on the north extension of the Annie vein in an area which has seen no exploration or mining of any kind. A copy of the geochemical and drillhole map is included.

Hole GSA-1

This hole penetrated the heart of the strong geochemical anomaly which strikes northwestward and was believed to represent the

extension of the Annie vein. However, no silicified vuggy vein material was found and only weak quartz-alunite alteration near the bottom of the hole. The quartz-latite porphyry, found throughout the hole, shows strong chlorite-montmorillonite alteration and is usually strongly brecciated with the fragments cemented by quartz, calcite, and pyrite with occasional copper sulphide, which is very likely enargite. The only structure approaching that of a vein was from 98'-108', where a silicified fault zone was found. The assay from 103'-108' was .022 oz Au, .10 oz Ag, and .11% Cu.

Three assays from a typical section of brecciated quartz latite porphyry with abundant pyrite and some enargite were run. These showed only minor gold and silver, but a composite ran .084% Cu. Although this copper content is far from ore-grade, it is nevertheless very appreciable, and, based on visual logging, a large portion of this hole will very likely assay similarly. This disseminated copper content over a width of at least 200 feet could easily be the cause of the geochemical anomaly and most likely is the cause.

Hole GSA-2

This hole again penetrated the heart of the geochemical anomaly and was continued an extra distance to the northeast to be

certain of not missing a vein in case the Cropsy Creek fault displacement was greater than expected. As with Hole GSA-1, no silica vein was found, but the quartz latite porphyry showed strong brecciation and argillic alteration for the first 320 feet, with the breccia cemented with quartz, calcite, and 5-10% pyrite. Disseminated enargite can be seen throughout. Two samples were assayed and one showed no copper and the other .13% Cu. It is estimated that much of the breccia zone would assay close to 0.1% Cu. It is quite apparent that the substantial width of disseminated copper sulphides has accounted for the geochemical anomaly. Since the gold-silver content is also low, there was no justification for drilling the 3rd authorized hole farther northwest.

ORE RESERVES

All sulphide ore reserves are put in the probable category, although a portion might be classed as positive. In line with past OME practice, no possible reserves are included in the figures. On the long-section, this is Block T-5. The oxide reserves are also classed as probable. No distinction was made for the portions mineable by open-pit or underground methods, but it is believed that a substantial portion of the oxide may be mined by open-pit methods. These reserves are

shown as Blocks T-1, T-2, and T-3. Blocks T-4 and T-6 should be ignored as they are possible blocks.

A tonnage factor of 11 cubic feet/ton is employed. Metal prices used are those in effect at the present time: Oct., 1967

Gold $35/oz, Silver $1.74/oz, and copper 38¢/lb.

Respectfully submitted,

Charles E. Melbye
