DEC 17 1971
Denver, Colorado

Memorandum

To: Chief, Washington TRU

From: Chief, Office of Minerals Exploration

Subject: Request to open file material on San Mateo Dome Project, McKinley County, New Mexico

Please prepare for open file release the enclosed material which is identified in the following proposed draft of a press release. Permission to release this material is indicated in the enclosed letter from the E. J. Longyear Company.

The U. S. Geological Survey is releasing in open files the following report and material prepared by the E. J. Longyear Company under a Defense Minerals Exploration Administration contract in 1958 and 1959. Copies are available for inspection in the Geological Survey Libraries, 1033 GS Building, Washington, D. C. 20242, and 1012 Federal Building, Denver, Colorado 30202.

Final Report (March, 1959)

Re: Docket No. 4842 (Uranium)
Contract No. Idm-E1183
San Mateo Dome Project
E. J. Longyear Company, Agent
(San Mateo Dome Project)
McKinley County, New Mexico

Gentlemen:

The following is submitted as a Final Report on results of work completed on the San Mateo Dome Project, McKinley County, New Mexico, under DMEA Contract Idm-E1183.

INTRODUCTION

An application for assistance on a drilling program was first submitted to the Defense Minerals Exploration Administration in October of 1957. The application was approved in April, 1958 and a Contract with the Government was signed allowing for some 23 holes to be drilled in two stages of drilling, Stage II (10 holes) to be drilled only if Stage I results warranted and Government approval was given in writing. Government participation was to be at 75%. The approved program covered drilling in sections 27, 33, and 34, T. 14N., R. 8W., and sections 3 and 4, T. 13 N., R. 8W., NMPM, McKinley County, New Mexico.

In April, 1958 a second DMEA application was submitted covering a drilling program in the E $\frac{1}{2}$ of section 32, T. 14 N., R. 8 W., NMPM, McKinley County, New Mexico. The drilling covered all of the area in the E $\frac{1}{2}$ of the section south of the mesa slope, on a spacing of approximately 700 feet. Government participation was to be at 50%.

On June 28, 1958, an Amendment was made to the existing Contract (Idm-E1183), providing for additional work and funds as requested in the application of April, 1958. The Government Contract, as amended, covered

drilling 40 exploratory holes at an estimated cost of $176,770.00, of which the Government would contribute up to $114,235.00. The additional work allowed drilling up to 17 holes in the E ½ of section 32 in two stages of drilling.

The overall program (40 holes) was to be carried out in four stages of drilling. Stages I and III were to be drilled first, Stages II and IV to be drilled only if results of drilling in Stages I and III warranted, and Government approval was given in writing. Drilling under the Contract commenced May 13, 1958.

GENERAL GEOLOGY

For details of straigraphy and structure in the area of which the San Mateo Dome Project is a part, reference is made to V. C. Kelley's Report on Geology and Uranium Possibilities of the San Mateo Dome Area, McKinley County, New Mexico. Mr. Kelley's Report was previously submitted to DMEA as Appendices to the applications for DMEA assistance which resulted in the Contract covered by this report. A general picture of the geology follows.

Stratigraphy

The rocks exposed in the San Mateo Dome area are the Mesaverde Group of Upper Cretaceous age. The broad valleys throughout the area and the steep canyons on the west and south are in the Mulatto shale member of the Crevasse Canyon formation. Covering most of the center and the western edge of the area steep cliffs occur, composed in ascending order, of the flat-lying Dalton sandstone and Gibson coal members of the Crevasse Canyon formation, and capped by the Point Lookout sandstone. Unexposed but lying below the Mulatto shale, in descending order, are the Dilco coal members of the Crevasse Canyon formation, Gallup sandstone, Mancos shale, and Dakota sandstone (Upper Cretaceous); Brushy Basin member of the Morrison formation (Jurrasic), the Westwater Canyon member of the Morrison (an upper Westwater Canyon sandstone lens intertongues with the overlying Brushy Basin shale in parts of the area, and is locally known as the Poison Canyon sandstone); and the Recapture Creek member of the Morrison formation.

The uranium ore deposits of the Ambrosia Lake area occur in the main body of the Westwater Canyon member of the Morrison formation and also in the Poison Canyon sand-tongue. In the San Mateo Dome area mineralization has been noted only in the Poison Canyon sand-tongue.

Structure

Reconnaissance drilling on the San Mateo Dome has confirmed the existence of an assymmetrical dome of post-Cretaceous age. Offset drilling in section 32 suggests that the axis of the dome passes through the center

of that section in a northeast direction. The dome is broken by numerous northeast-trending faults. Other faults with a different trend, not apparent on the surface, are indicated by drill hole information, as is pre-Cretaceous folding in the Morrison formation.

EXPLORATION

On May 13, 1958, drilling on the San Mateo Dome Project, under DMEA Contract Idm-E1183 was initiated. Drilling was continuous through October 24, 1958, at which time Stages I and III were completed. Results of drilling in Stages I and III did not justify completing Stages II and IV; however, a request was made on November 1, 1958 for an amendment to the Contract to allow for further drilling in the W ½ of section 32 (see Fig. 1 attached). The request was for 6 holes. On December 9, 1958, tentative approval was given by the Government to drill 2 of the requested holes, with the provision to be made for additional holes should either of the first 2 penetrate ore-grade material. Because executed Consents to Lien forms covering additional ground to be subordinated under the Contract could not be obtained from all parties concerned, the request of November 1, 1958, was withdrawn on February 17, 1959.

During the term of the Contract, 45,016 feet were drilled in 22 completed holes. Total cost of the project was approximately $98,147.79, of which the Government contributed approximately $63,294.50.

Details of drilling, probing, and sampling under each Stage of the work follows.

Drilling

All holes were drilled by Scott Bros. Drilling Company of Grants, New Mexico, with a Failing truck-mounted Model 1500 drill rig and using 4 3/4 inch bits. When coring, a 4 inch bit was used to get a 2 5/16 inch core. Samples of drill cuttings indicated that all holes penetrated the Recapture member of the Morrison formation at least 20 feet.

Of the 45,016 feet drilled only 44,851 feet were submitted to the Government for reimbursement. The difference is explained by the fact that some of the holes penetrated the Recapture more than 20 feet and the Government only recognized depths up to 20 feet into the Recapture member.

Stage I - Drilling commenced May 13, 1958 and was completed September 10, 1958. A total of 26,376 feet were drilled in 13 completed holes (see Drill Hole Data Sheet attached). One hole was drilled in section 33, 5 in section 4, 2 in section 3, 4 in section 27, and 1 in section 34 (see attached Fig. 1 for hole locations).

Two holes, G-1-33 and G-9-27, were cored through the Westwater member. Total feet cored were 591; 334 feet in hole G-1-33, and 257 feet in hole G-9-27.

A total of 25,500 feet of non-core drilling and 700 feet of core drilling was allowed by the Contract. Of the 26,376 feet drilled, 26,261 feet were submitted to DMEA for reimbursement. The excess footage turned in was approved by DMEA by letter of November 10, 1958, to the San Mateo Dome Project from Mr. J. W. Townsend; the footage being covered by a transfer from that footage allowed under Stage II drilling.

Stage II - Results of Stage I drilling did not justify continuing with Stage II drilling, therefore no work was done under Stage II.

Stage III - Drilling started September 8, and was completed October 24, 1958. A total of 18,640 feet were drilled in 9 completed holes (see Drill Hole Data Sheet attached). All holes were drilled in the E $\frac{1}{2}$ of section 32, spacing between holes being approximately 1000 feet north to south and 2000 feet east to west. None of the holes were cored. Of the 18,640 feet drilled, 18,590 feet were submitted to DMEA for reimbursement. The footage not submitted was deducted from the total because certain of the holes were drilled more than 20 feet into the Recapture member.

None of the holes penetrated ore-grade material.

Stage IV - Because Stage IV holes were to be drilled as offsets to Stage III holes that penetrated ore-grade material, no work was done under Stage IV.

Probing

All holes were probed by Century Geophysical Corporation of Tulsa, Oklahoma, using a truck-mounted Logging Control Unit, Model 2201. In each hole, there were recorded (when possible) three logs, gamma-ray, resistivity, and self-potential.

The geophysical logs indicated that all holes except one were drilled into the Recapture member at least 20 feet. The log on hole G-7-3 indicates that the Recapture was penetrated only 11 feet. The Drill Hole Date Sheet attached is a compilation of all data obtained from an interpretation of the gamma-ray, resistivity, and self-potential curves recorded on the geophysical logs. Because of their bulk (they are each 20 feet long) and the cost of reproduction, plus the fact that 5 copies of each log have previously been submitted, no logs will be submitted with this report. Should it be necessary that copies of the logs are needed arrangements can be made to submit them at a later date.

A total of 44,930 feet were probed in 22 completed holes. Of the total feet only 44,756 feet were submitted to DMEA for reimbursement. The difference is explained by the fact that some of the holes could not be probed to their entire depth because of caving, and by the fact that

some of the holes were drilled more than 20 feet into the Recapture but the Government only recognized depths up to 20 feet into the Recapture member.

Stage I - a total of 26,377 feet were logged in 13 completed holes. No above background radioactivity was recorded in any of the holes and all are considered barren (see Drill Hole Data Sheet attached).

The Westwater member ranges in thickness from 73 feet in hole G-7-3 to 202 feet in hole G-1-33. Average thickness is 132 feet. The Poison Canyon sand is thought to be present only in holes G-3-4 and G-4-4. In most of the other holes there exists several shale splits within what is interpreted as the Westwater and it is possible that the upper sand beds could be the Poison Canyon sand; however, this cannot be determined because of the distance between holes which makes correlation difficult, and the entire interval is called the Westwater member.

Of the total feet probed, only 26,166 feet were submitted for reimbursement.

Stage II - No holes were drilled under Stage II.

Stage III - A total of 18,653 feet were logged in 9 completed holes. No above background radioactivity was recorded in 7 of the 9 holes probed, indicating that they are barren. Two of the holes, G-15-32 and G-16-32, contained above background radioactivity and are considered mineralized. The indicated mineralization is in the Poison Canyon sand at a depth of approximately 1880 feet. Only slight mineralization, amounting to an estimated 1 - 3 feet of 0.03 -0.04% eU308 is indicated (see Drill Hole Data Sheet attached).

The Westwater member ranges in thickness from 106 feet in hole G-16-32 to 211 feet in hole G-22-32. Average thickness is 151 feet. The Poison Canyon sand unit is present in all but 3 holes. Average thickness of the Poison Canyon sand is approximately 50 feet. Thickness of the sand has no noticeable effect on the mineralization.

Of the total feet probed, only 18,590 feet were submitted to DMEA for reimbursement.

Stage IV - No holes were drilled under Stage IV.

Sampling

Dust and/or sludge samples were collected from every 10 feet of hole drilled. The samples were logged by a geologist and those through the Westwater were checked for radioactivity with a geiger counter. None

of the samples checked showed radioactivity above background. Samples through the Westwater were sacked and saved for study by the Government.

Contacts cannot be definitely determined from samples because of contamination. Therefore, there exists some discrepancies between contacts picked from a study of the sludge samples and those picked from the geophysical logs. This difference is not great; however, contacts used as reference points are taken from geophysical logs because of their greater accuracy. In all holes drilled sludge samples indicated that the Recapture member had been penetrated at least 20 feet.

When core drilling, all core was checked for radioactivity, stored in core boxes, and saved for future study. No samples were deemed worthy of chemical assay.

Stage I - Core and sludge samples from the holes indicate that bleached Westwater sand in excess of 100 foot thicknesses is present, and that coarse grained sand zones exist in the Westwater. In spite of these favorable conditions, gamma-ray logs show that all holes contain no above background radioactivity.

Stage II - No samples taken.

Stage III - As in Stage I sampling, sludge samples indicate that bleached Westwater sand in excess of 100 feet thicknesses is present, and that coarse grained sand zones exist in the Westwater. However, 7 of 9 holes are shown to be barren by the geophysical logs. In none of the holes were samples deemed worthy of chemical assay. Neither the samples from the barren holes nor the mineralized holes showed any above background radioactivity when checked with a geiger counter.

Stage IV - No samples taken.

Summary of Costs

Actual Costs (Stage I)

Category (1) Independent Contracts	Cost to SMDP	Cost submitted to DMEA
19,500 feet of non-core drilling 0-1,500 ft. depths, @ $1.50/ft.	$29,250,00	$29,250.00
6,285 ft. of non-core drilling,1,500 -2,200 ft. depths, @ $2.25/ft.	14,141.25	13,882.50
591 feet core drilling,1,600-2,200 ft. depths, @ $13.00/ft.	7,683.00	7,683.00

Category (1) Independent Contracts	Cost to SMDP	Cost submitted to DMEA
5.5 hours drill crew standby time @ $15.00/hr.	82.50	82.50
26,377 feet probing and logging @ $ 0.115/ft.	2,971.55	2,958.95
18.6 logging crew stand-by time @ $10.00/hr.	186.00	86.00
Cost of lost circulation material in excess of $100.00/hole (13 holes)	497.10	82.00
42 hrs. bulldozing @ $14.00/hr.	630.00	570.00
Categories (2) through (6) None		
Category (7) Miscellaneous		
70 cardboard core boxes @ $1.17 each	82.13	82.13
Chemical analyses - none taken		
Fixed Unit Costs		
Incidental allowance for each foot of hole drilled, 26,376 feet @ $0.18/ft.	4,747.68	4,726.98
TOTAL COST OF STAGE I	$60,271.21	$59,404.06

Actual Costs (Stage III)

Category (1) Independent Contracts	Cost to SMDP	Cost submitted to DMEA
13,500 feet non-core drilling 0-1,500 ft. depths @ $1.50/ft.	20,250.00	20,250.00
5,140 feet non-core drilling 1,500-2,200 ft. depths, @ $2.25/ft.	11,565.00	11,452.50
22.5 hrs. drill crew stand-by time @ $15.00/hr.	337.50	135.00
18,653 feet probing and logging @ $ 0.115/ft.	2,055.98	2,045.23
9 hrs. logging crew stand-by @ $10.00/hr. & $17.00/hr.	102.90	74.00

	Cost to SMDP	Cost submitted to DMEA
Cost for lost circulation material in excess of $100.00/hole - none		
14 hrs. bulldozing @ $15.00/hr.	210.00	180.00
Categories (2) through (6) None		
Fixed Unit Costs		
Incidental allowance for each foot of hole drilled, 18,640 ft. @ $0.18/ft.	3,355.20	3,346.20
TOTAL COST OF STAGE III	$ 37,876.58	$37,482.93
TOTAL COST STAGE I & STAGE III.....	$ 98,147.79	$96,886.99
GOVERNMENT PARTICIPATION.....		$63,294.50

SUMMARY AND CONCLUSIONS

A total of 45,016 feet were drilled in 22 completed holes, in two stages of drilling. Stage I drilling was distributed over an area covering approximately three land sections with holes being drilled in each of five different sections. An evaluation of results of Stage I drilling indicate that all of the holes are barren and that there is no justification for further drilling in that area. Stage III drilling was distributed over an area covering only ½ section. An evaluation of results show two holes to be mineralized and seven holes to be barren. The two mineralized holes are 1000 feet apart with no holes between them, and although the mineralization encountered cannot be considered ore-grade, it does indicate the presence of near by ore-grade material. However, mineralization noted in holes SM 2-32 and SM 29-32, located immediately to the west and on the northeast end of a presently known ore zone where the known ore appears to be thinning out, indicates that the mineralization noted in holes G-15-32 and G-16-32 is probably a halo around the known ore to the west rather than mineralization on the sides of an eastern extension of that ore.

Sincerely yours,
