ABSTRACT

The design of a microprocessor-based data logger, which collects and digitizes analog voltage signals from a continuous-measuring instrumentation system and transmits serial data to a magnetic tape recorder, is discussed. The data logger was assembled from commercially-available components and can be user-programmed for greater flexibility. A description of the data logger hardware and software designs, general operating instructions, the microprocessor program listing, and electrical schematic diagrams are presented.

INTRODUCTION

This report describes the multi-channel data logger (DL) which records signals from the continuous water-sampling and -analysis systems on the U.S.Geological Survey-operated vessels: R/V Polaris and R/V Estero (Schemel and Dedini 1979; Dedini and Schemel 1980). The DL is an adaptation of the microprocessor based wind-prospecting system designed by Leap (1980). Up to 16 channels of analog signals are sampled and converted to digital data by the DL. A serial interface receives digital data from a fathometer. The DL transmits data and time from an internal clock to a tape recorder (Md 4923, Tektronix, Inc., Beaverton, Oregon)1/ via a serial interface (RS-232) at user selected time intervals. The tape recorder is compatible with certain computer systems.

At the time of design and fabrication, no commercially available data logger could meet our requirements without extensive modification. In particular, specialized hardware-interfaces are required to match the outputs of the water-analysis systems and to resolve the required number of significant digits. The user-programmable microprocessor allows for greater flexibility for future modification as our requirements change.

The text of this report is limited to a description of the hardware and software designs; additional relevant information can be found in Leap (1980). Operating instructions, a glossary, a program listing, and circuit diagrams make up the Appendix.

1/ The mention of brand names is for identification purpose and does not constitute endorsement by the authors or the U.S. Geological Survey.

HARDWARE CONFIGUATION

The data logger utilizes a microprocessor (CDP 1802, RCA Solid State, Somerville, NJ). The microprocessor combined with memory and input-output controllers form a microcomputer. The 16 analog channels are multiplexed, digitized by a 12-bit A/D converter, then read by the microcomputer for further processing (Fig.1) The serial input port converts serial data from a fathometer to parallel data for input to the microcomputer. Data sampling rates and data processing are determined by the microcomputer software and switch settings on the front panel of the logger (Fig.2). Data are transmitted via a RS-232 output port to the recorder. The format and frequency of the data transmissions are also determined by software and switch settings.

The data logger was fabricated in modules that are functionally and physically on separate circuit cards. Figure 3 shows how the modules are integrated into the system. Each of the 10 modules shown in Fig.3, is described in the text of this report. The hardware is contained in a metal cabinet that is 12" wide by 12" deep by 7" high. The following is a brief description of the front panel switches and displays (Fig.2) and the rear panel connections and their functions. Connections to the front panel components are detailed at the end of the hardware configuration section.

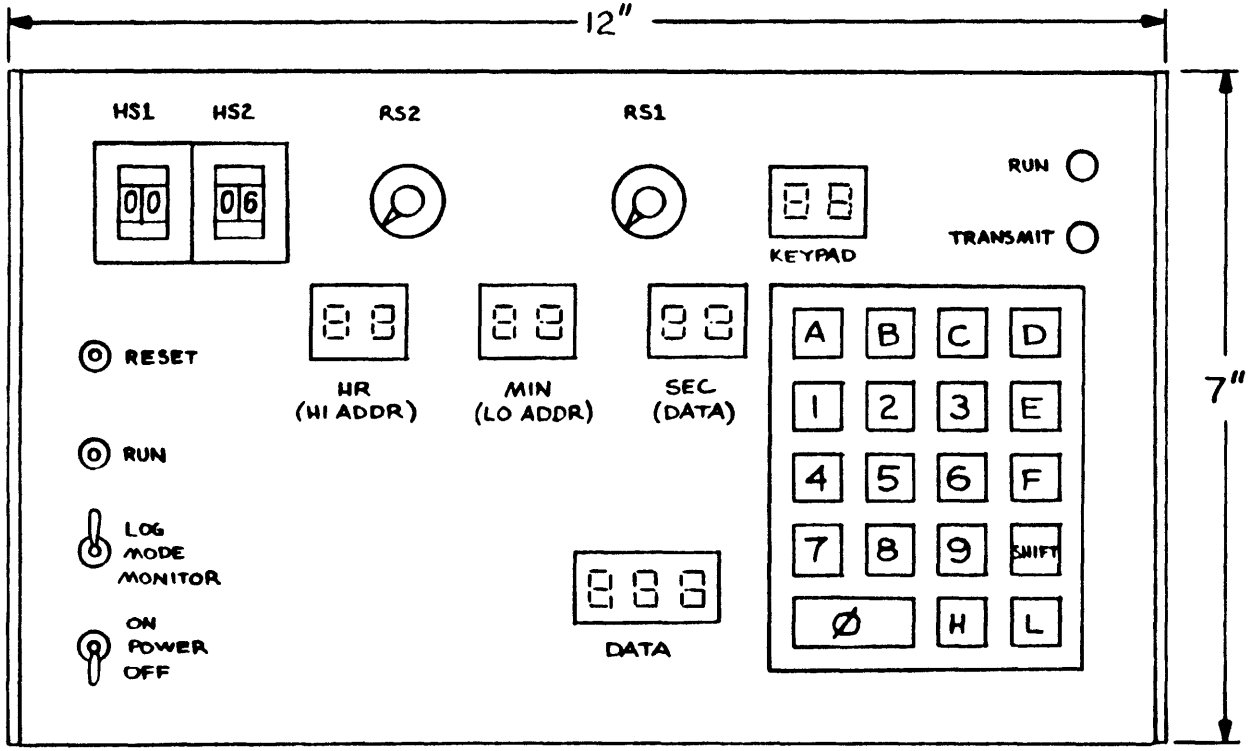

Figure 2

Data Logger Front Panel

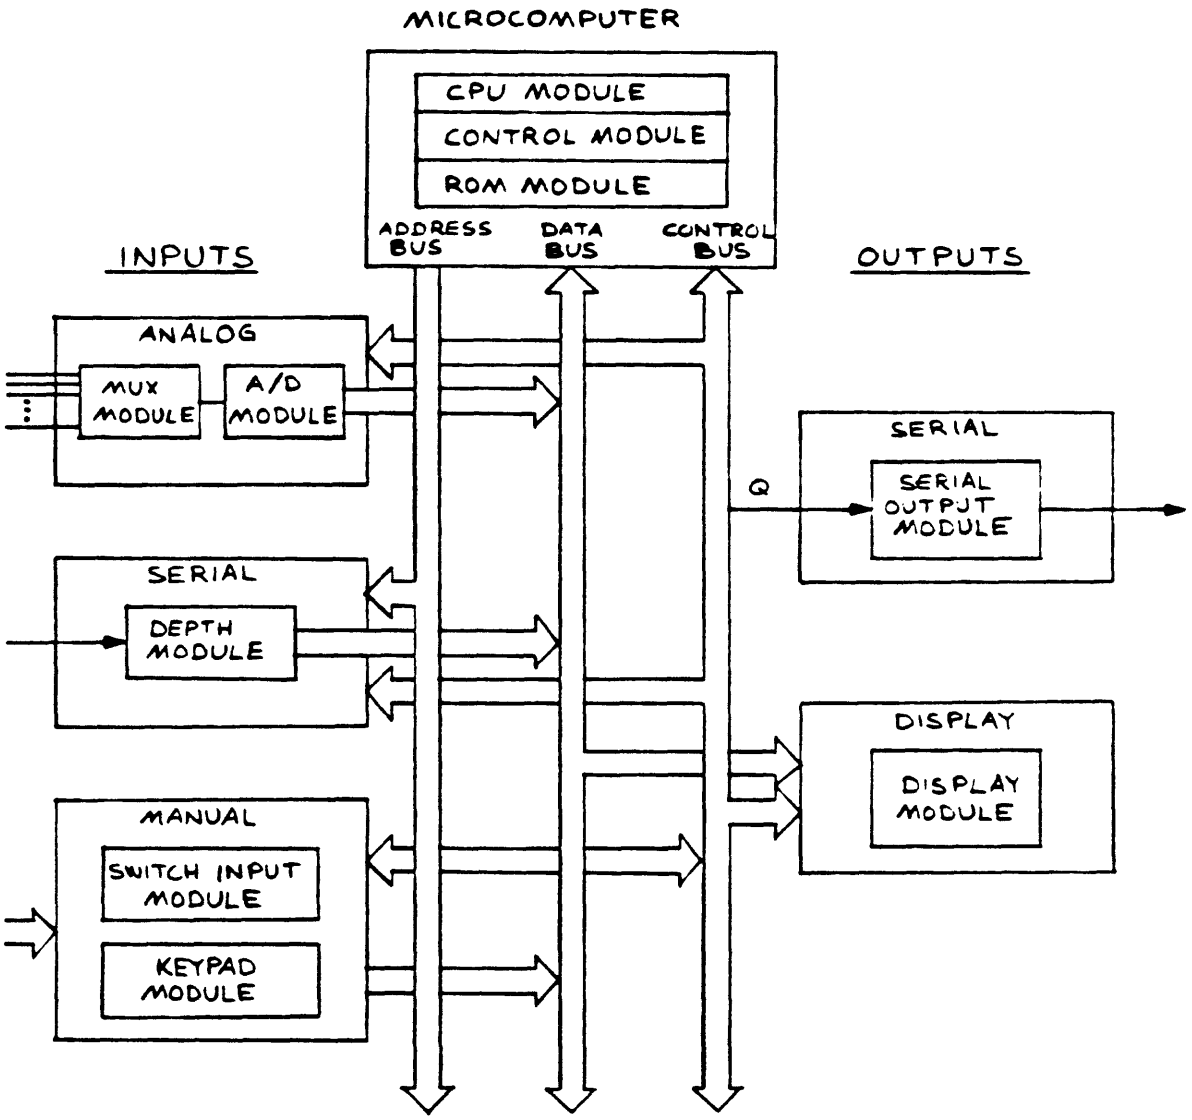

Figure 3

Block Diagram of the Data Logger

DESCRIPTION OF FRONT PANEL

MODE SWITCH - The DL has two modes of operation determined by a switch on the front panel. In the LOG mode the logger collects data and transmits them over the serial interface. In the MONITOR mode the microcomputer executes a program determined by the user. In the present configuration a program which sets the real-time clock is executed when the DL is placed in the MONITOR mode.

RUN SWITCH - Pressing the "RUN" switch executes the program when the DL is in the MONITOR mode.

RESET SWITCH - The "RESET" switch will manually reset the DL when running a program in the MONITOR mode. The following digits will then appear on the panel display: 03 00 30.

SCAN INTERVAL SWITCH - Hexadecimal switch HS2 selects the scan interval, which is the frequency at which the DL transmits data and time to the tape recorder. The scan interval (in seconds) is equal to the HS2 switch setting multiplied by 5. For example, if HS2 is set on "06", then data are transmitted every 30 seconds.

KEYPAD - In the MONITOR mode the keypad is used to enter address and data information. The keypad can also be used for the operation of an executed program. In the LOG mode the keypad is used for selecting an analog data channel to be displayed in the DATA display (see below).

TRANSMIT LIGHT - The "TRANSMIT" light is on when serial data are transmitted to the tape recorder.

RUN LIGHT - The "RUN" light indicates that the microcomputer is in the RUN mode. This light will also blink once every five seconds when the logger is in in the LOG mode, because the microcomputer is in a RESET mode.
DISPLAYS - In the MONITOR mode, the DL high address, low address, and data will appear on the HR/HI ADDR, and MIN/LO ADDR, and SEC/DATA displays, respectively. In the LOG mode, the real-time clock will be displayed. The keypad display shows the last two keys (0-F) that were pressed. The DATA display shows, the signal from one of the analog channel inputs in 12-bit hexadecimal notation; this channel (0-15) is selected by pressing one of the keys (0-F). Data appear every five seconds.

DESCRIPTION OF REAR PANEL

POWER SOURCE - The DL requires a 115VAC, 60Hz power source. The case is earth grounded.
CONNECTIONS - A 25-pin male terminal connector J1 (type DB-25P), is the 16 analog-signal input. The analog-signal input voltage range to the DL is -0.5V to +4.5V. A 25-pin female terminal connector J2 (type DB-25S), is the RS-232 serial output to the tape recorder. A 4-pin female terminal connector J3 (Molex type), is the connection to the fathometer.

BUS STRUCTURE

Most of the connections between the 10 modules of the data logger are made via a 44-pin bus. Bus pin numbers and connections to the microprocessor chip are shown in Table 1, along with the corresponding 1802 signal name.

Following are brief functional descriptions of some of the 1802 signals that are used in this system.

1802 Signals:

$\overline{EF1}$ - $\overline{EF4}$	These are four inputs to the microprocessor, controlled by keypad inputs and tested by branch instructions.
A0 - A7	These are the eight memory-address lines. They provide the 16-bit memory-address in the form of two successive 8-bit bytes. These bus lines are buffered by the CPU module.
TPA	This is a timing signal; one function is to latch one byte of the multiplexed address.
TPB	One of the functions of this timing signal is to take memory data from the bus during an output instruction.
N0 - N2	This 3-bit code is generated by the input/output instruction and is used by this system to select one of seven input or output ports.
D0 - D7	These eight lines form the 8-bit bidirectional data bus.
$\overline{MWR}$, $\overline{MRD}$	The state of these two lines determines whether a byte is to be read from the address memory location, written into it, or neither.
$\overline{INT}$	This is the interrupt line. An interrupt is used to advance the software-controlled real-time clock.
SC0, SC1	These signals form the 2-bit state code, which permits synchronization of I/O circuits with the microprocessor operating instructions.
Q	This output flag is toggled (having either one of two states at a given time) under program control to provide serial data output.

Table 1

Bus-Signal Pin Assignments

Signal name	Bus pin number	CPU pin number	Signal name	Bus pin number	CPU pin number
$\overline{\text{EF4}}$	1	21	NO	A	19
$\overline{\text{EF3}}$	2	22	N1	B	18

XTAL	19	39	CLOCK	W	1
$\overline{\text{EXT CLEAR}}$	20			X	
$\overline{\text{WAIT}}$	21	2		Y	
GND	22	20	GND	Z	20

Clock — A single-phase clock input on this line determines the operating speed of the microprocessor. a 1.78 MHz signal from the control module provides the clock input.

The following external signals are not 1802 signals but are signals peculiar to this system that are also found on the system bus.

External Signals:

$\overline{\text{EXT CLEAR}}$ — This signal directly controls the RUN and RESET mode of the microprocessor. When $\overline{\text{EXT CLEAR}}$ =1, the microprocessor is in the RUN mode. When $\overline{\text{EXT CLEAR}}$ =0, the microprocessor is in the RESET mode. $\overline{\text{EXT CLEAR}}$ is also used to "enable" the RAM.

VBAT — A continuous 5 volts DC from the power module is supplied on this line.

$\overline{\text{STROBE}}$ — This signal is generated by the control module. When $\overline{\text{STROBE}}$ is low, 5 volts is applied to VSTB. (Not used in present configuration.)

VSTB — The CPU module is power-strobed by VSTB; it is activated when $\overline{\text{STROBE}}$ is low. (Not used in present configuration.)

GND — GND is the common voltage for all of the circuitry and is isolated from earth ground and chassis.

CONTROL MODULE

The control module controls the LOG and MONITOR modes of the data logger and the RUN and RESET modes of the microprocessor, provides a clock input for the microprocessor, and issues interrupts.

The data logger has two modes of operation determined by a switch on the front panel. In the LOG mode the logger collects data and transmits them over the serial interface. In the MONITOR mode the microcomputer executes programs chosen by the user. In the present configuration the program which sets the real-time clock is executed when the logger is in the MONITOR mode.

LOG mode. In the LOG mode the microcomputer operates in five-second cycles. A cycle begins with the positive transition of the START signal (refer to Fig.4). Two cycles (of the 60 Hz clock) after the START signal goes high $\overline{\text{EXT CLEAR}}$ goes high. (The microcomputer is in the RUN mode when $\overline{\text{EXT CLEAR}}$=1 and in the RESET mode when $\overline{\text{EXT CLEAR}}$=0.) The microcomputer executes the data-logging program while in the RUN mode (i.e., when $\overline{\text{EXT CLEAR}}$=1) until the execution of the OUT 6 instruction. This instruction triggers the INTERNAL RESET signal, which puts the microcomputer back in the RESET mode ($\overline{\text{EXT CLEAR}}$=0). The microcomputer remains in the RESET mode until the next positive transition of the START signal, then the cycle is repeated.

The $\overline{\text{CLR}}$ signal is inserted after the positive transition of the START signal. This is to make sure that the computer is reset every five seconds; it prevents the microcomputer from

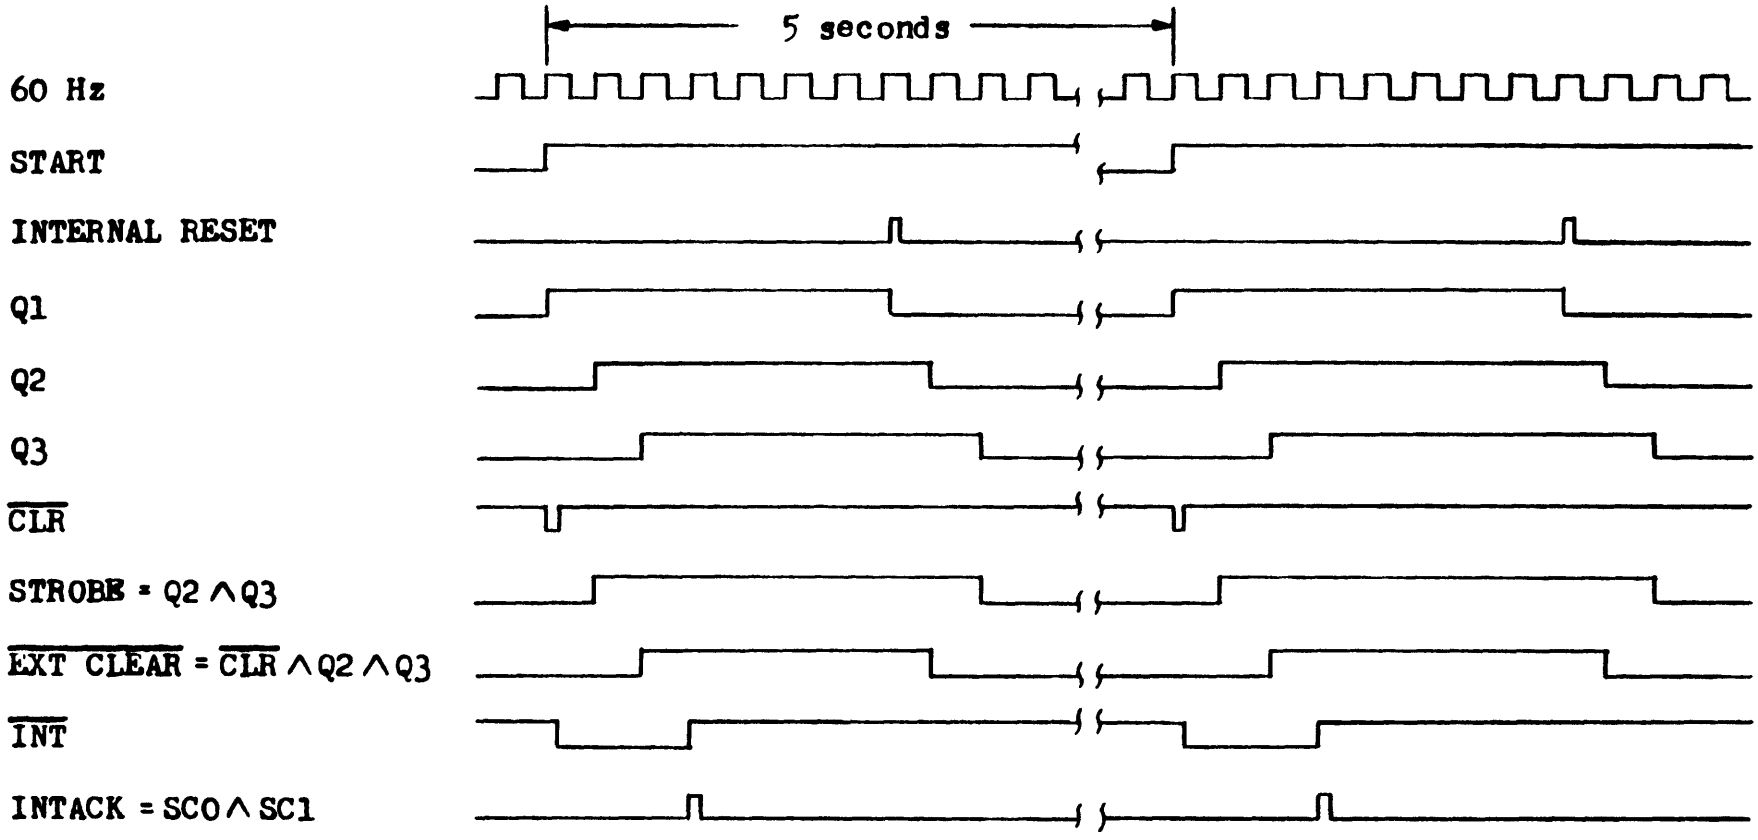

Figure 4

Timing Diagram for the Control Module
in the LOG Mode

being "hung" in a loop due to erroneous program execution. The $\overline{CLR}$ signal has no effect during a normal cycle because the microcomputer is already in the RESET mode when $\overline{CLR}$ is asserted.

The $\overline{INT}$ signal (interrupt request) is also asserted during the positive transition of the START signal. $\overline{INT}$ is held low until the interrupt is serviced (i.e., when INTACK goes high).

The $\overline{STROBE}$ signal is not used in the present configuration of the data logger. The signal is used in low power-consumption applications requiring power strobing of the CPU and other modules.

MONITOR mode. The only "hardware" difference between the MONITOR and LOG modes is that in the MONITOR mode the $\overline{CLR}$ signal is disabled. This allows the microcomputer to be in the RUN mode continuously without being reset every five seconds. The microcomputer can be reset with the INTERNAL RESET signal (under software control) but this is not typically done in the MONITOR mode. Interrupts occur at five-second intervals as in the LOG mode. This allows the interrupt driven clock to function in both the LOG and MONITOR modes. (See Fig.5 for a timing diagram for the control module in the MONITOR mode.)

CPU AND ROM MODULES

The CPU (Central Processing Unit) module contains the microprocessor, 2048 bytes of EPROM, and 256 bytes of RAM. The program stack, the real-time clock, and a "scratchpad" storage are maintained in this RAM.

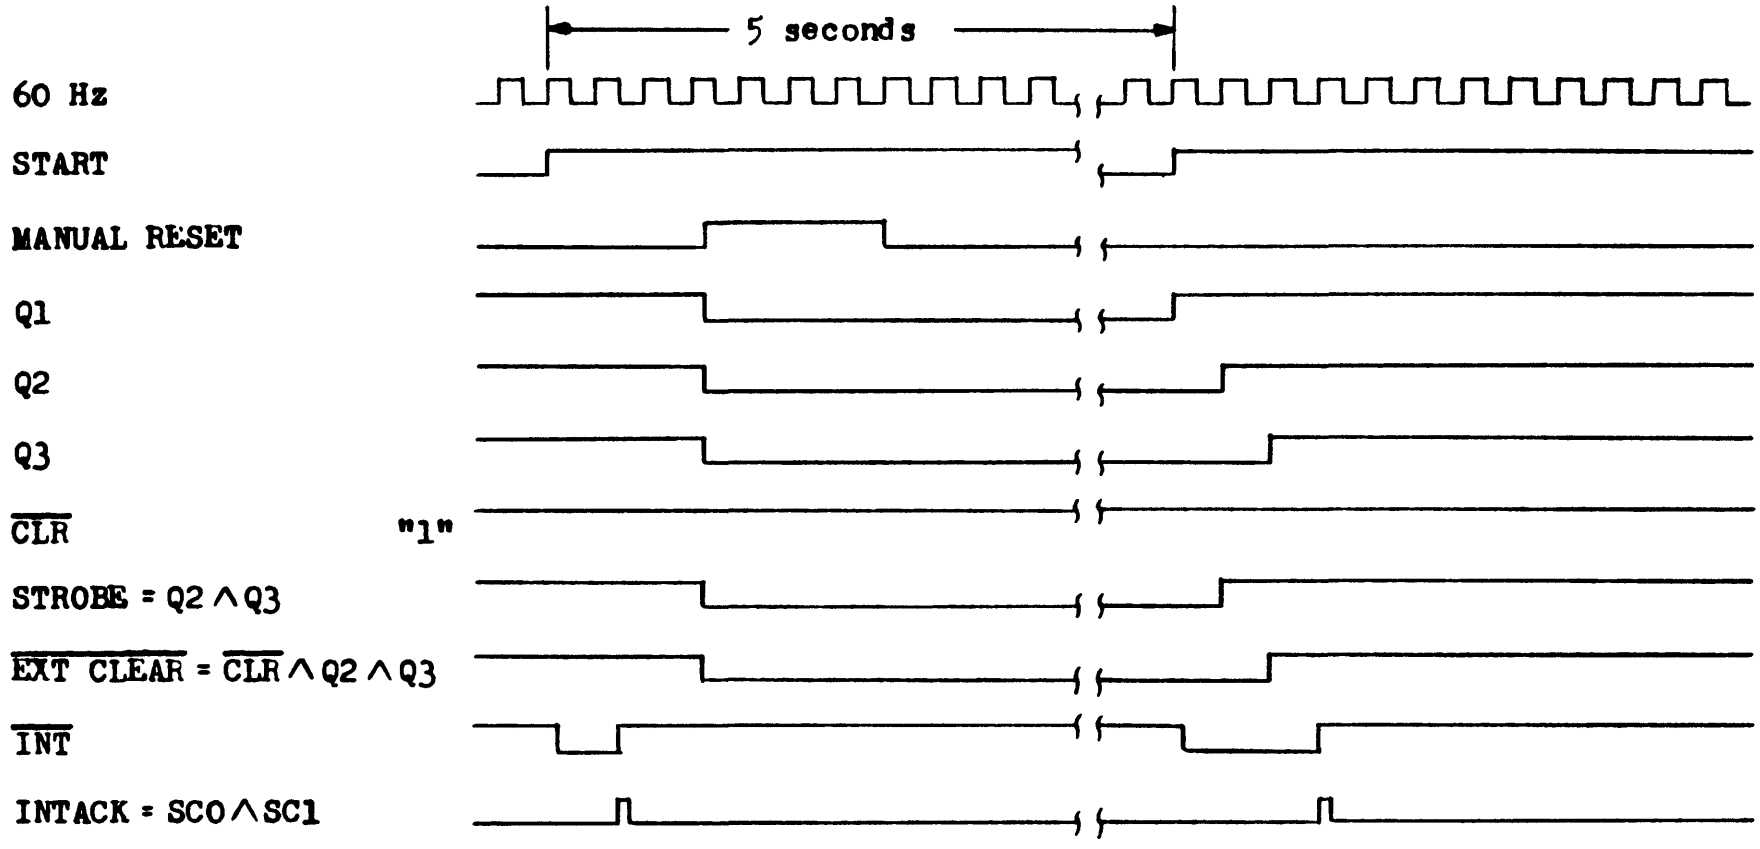

Figure 5

Timing Diagram for the Control Module
in the MONITOR Mode

The 16-bit memory address is multiplexed in the form of two 8-bit bytes. The high address byte appears on the address bus followed by the low byte. The high byte is strobed into an 8-bit register by the TBA timing signal so that the full 16-bit address is available to the memory devices as soon as the low byte appears on the address bus. The upper eight address bits are encoded to give the 256 bytes of RAM a starting address of 8C00. The upper five address bits are encoded to give the 2048 bytes of EPROM a starting address of 0000.

The ROM module consists of only a ROM chip and a power by-pass capacitor. The ROM (CDPR582, RCA Corporation, Somerville, NJ) provides subroutines used in programing the microprocessor (See RCA CDP 1802 Microprocessor User Manual). Pin assignments for the ROM are shown in Table 2.

MULTIPLEXER AND A/D MODULES

The multiplexer module selects one of the 16 analog signals from the data cable. The selected signal is offset by 0.5V and filtered. A 4-bit output port addresses the multiplexer for each one of the 16 analog signals. The output port latches the four most significant bits (D7 - D4 on the bus) from the OUT 5 instruction.

A three-stage op-amp circuit buffers, filters, and offsets the incoming signals. The circuit is a second-order low pass filter with a time constant of 1.0 microsecond. The filter rejects high frequency electronic noise. The time constant is small so that scan rates can be achieved. The output signal settles to 99.95 % of its final value 10 microseconds after the

(step) input signal is applied. The signal is offset by 0.5V. The steady state response of the filter is

$$V_{out} = V_{in} + 0.5\ V\ .$$

The A/D module takes the analog signal selected by the multiplexer module and performs a 12-bit analog-to-digital conversion in response to the OUT 7 instruction. The 12-bit word is read into the microcomputer with the INP 4 and INP 5 instructions. Table 3 shows how the module responds to the microprocessor's I/O instruction.

DEPTH MODULE

The depth module takes serial data from a fathometer (Md 2700, Datamarine, Pocasset, MA.) and converts them to parallel data for input to the microcomputer. A functional circuit diagram of the depth module is shown in Fig.6.

Input Signals. The $\overline{\text{CLOCK}}$ and $\overline{\text{DATA}}$ signals from the depth sounder are optically isolated from the depth module. The $\overline{\text{CLOCK}}$ signal directly drives the optical isolator, U1, with current-limiting resistor R1. The $\overline{\text{DATA}}$ signal is buffered with transistor Q1 to drive optical isolator U2.

A timing diagram of the $\overline{\text{CLOCK}}$ and $\overline{\text{DATA}}$ signals is shown in Fig.7. Serial data bits (inverted) are valid for one clock cycle following each negative transition of the clock. The $\overline{\text{CLOCK}}$ and $\overline{\text{DATA}}$ signals are isolated and inverted giving the CS and DS signals, respectively (refer to Fig.7). CS and DS lag behind the $\overline{\text{CLOCK}}$ and $\overline{\text{DATA}}$ signals because of rise and fall times of several microseconds at the outputs of the optical isolators. The times by which CS and DS lag the $\overline{\text{CLOCK}}$ and $\overline{\text{DATA}}$ signals,

Table 3

The Use of I/O Instructions
with the A/D Module

instruction	action
OUT 7	start A/D conversion
INP 4	4 most significant bits → $D_{3:0}$
INP 5	8 least significant bits → $D_{7:0}$

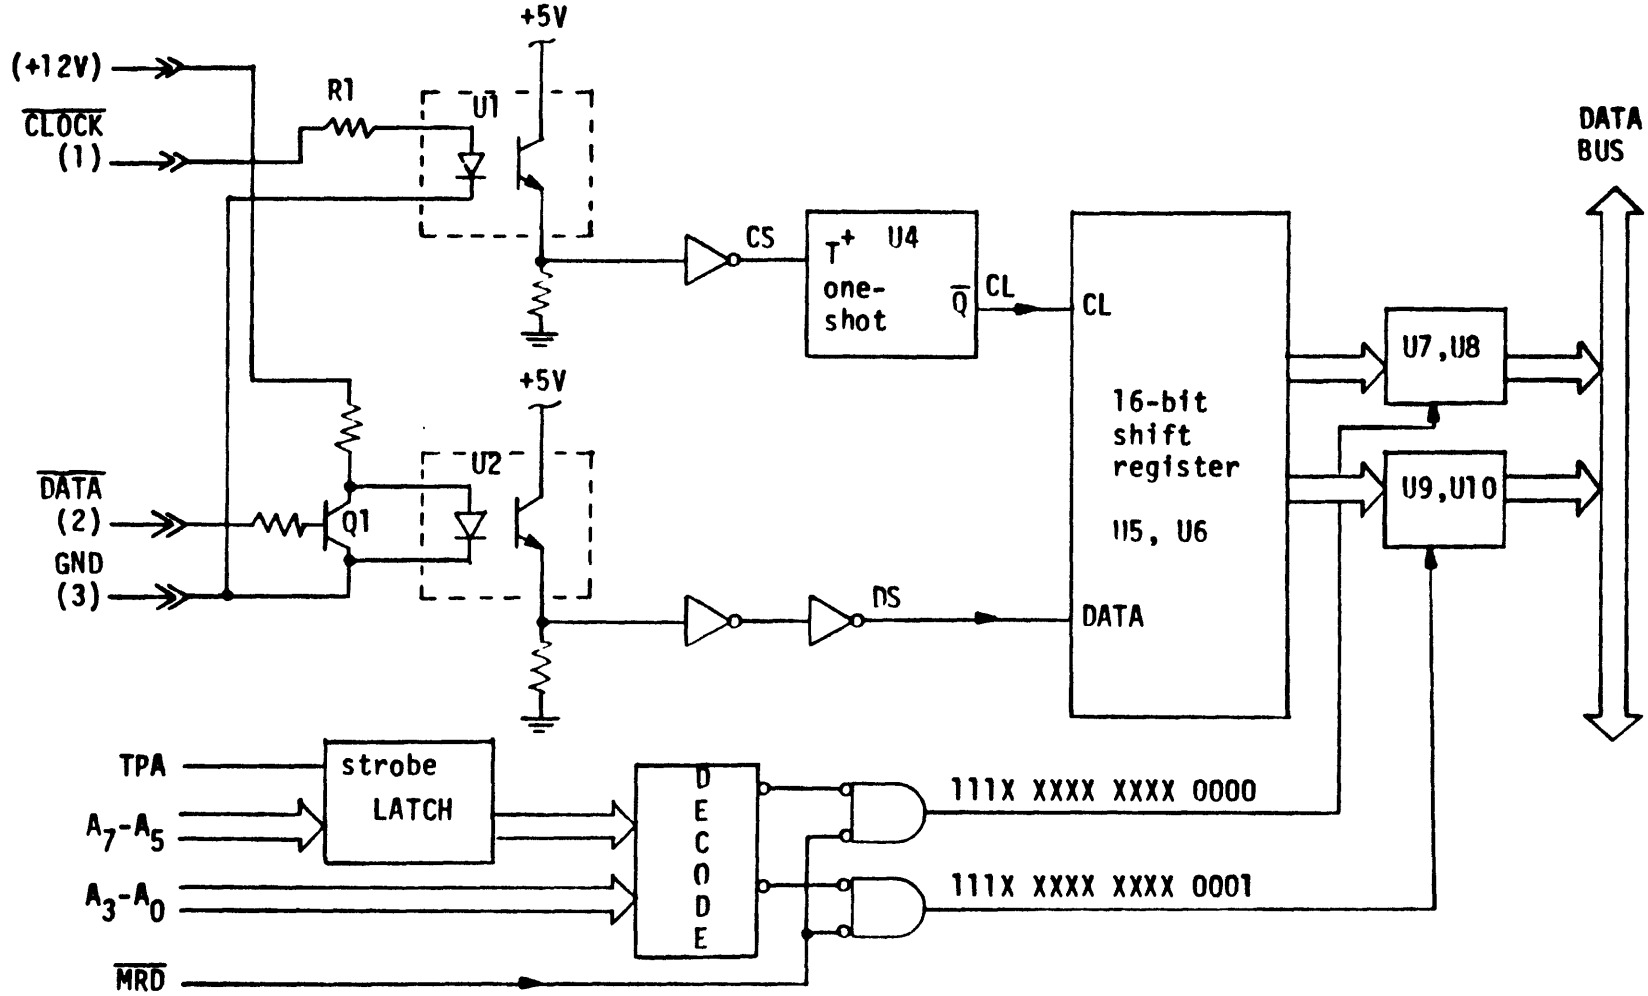

Figure 6

Depth Module Functional
Circuit Diagram

Timing Diagram for Depth Module
Input Signals

respectively, depend upon the characteristics of each optical isolator. The lag times of CS and DS cannot be assumed to be the same; therefore, CS cannot be used to clock data from DS into the shift register. This problem is corrected by shifting CS to approximate center of the time interval for which the corresponding data bit on DS is valid. The rising edge of CS is delayed by about 15 microseconds by a one-shot. The resulting signal, CL, is used to clock data from DS into the 16-bit shift register (See Fig.7).

Outputs. The 16-bit parallel data at the outputs of shift registers U5 and U6 are connected to bilateral switches U7-U10 (refer to Fig.6). Memory-mapped I/C is used to connect these 16 bits of data to the data bus eight at a time. Table 4 shows the information provided at each memory-mapped address.

DISPLAY AND I/O MODULES

In this section, the display, switch-input, keypad, and serial-output modules are described. These modules provide the data logger with its basic I/O capabilities.

Display Module. The display module is made up of five output ports which display hexadecimal or decimal numbers. Figure 8 indicates which output instructions provide the data for the front-panel displays.

Switch-Input Module. The switch-input module is used to read the positions of the rotory and hexadecimal switches on the front panel. The rotory switch positions are encoded by the module. Table 5 shows the correspondence between switches and input ports.

Table 4

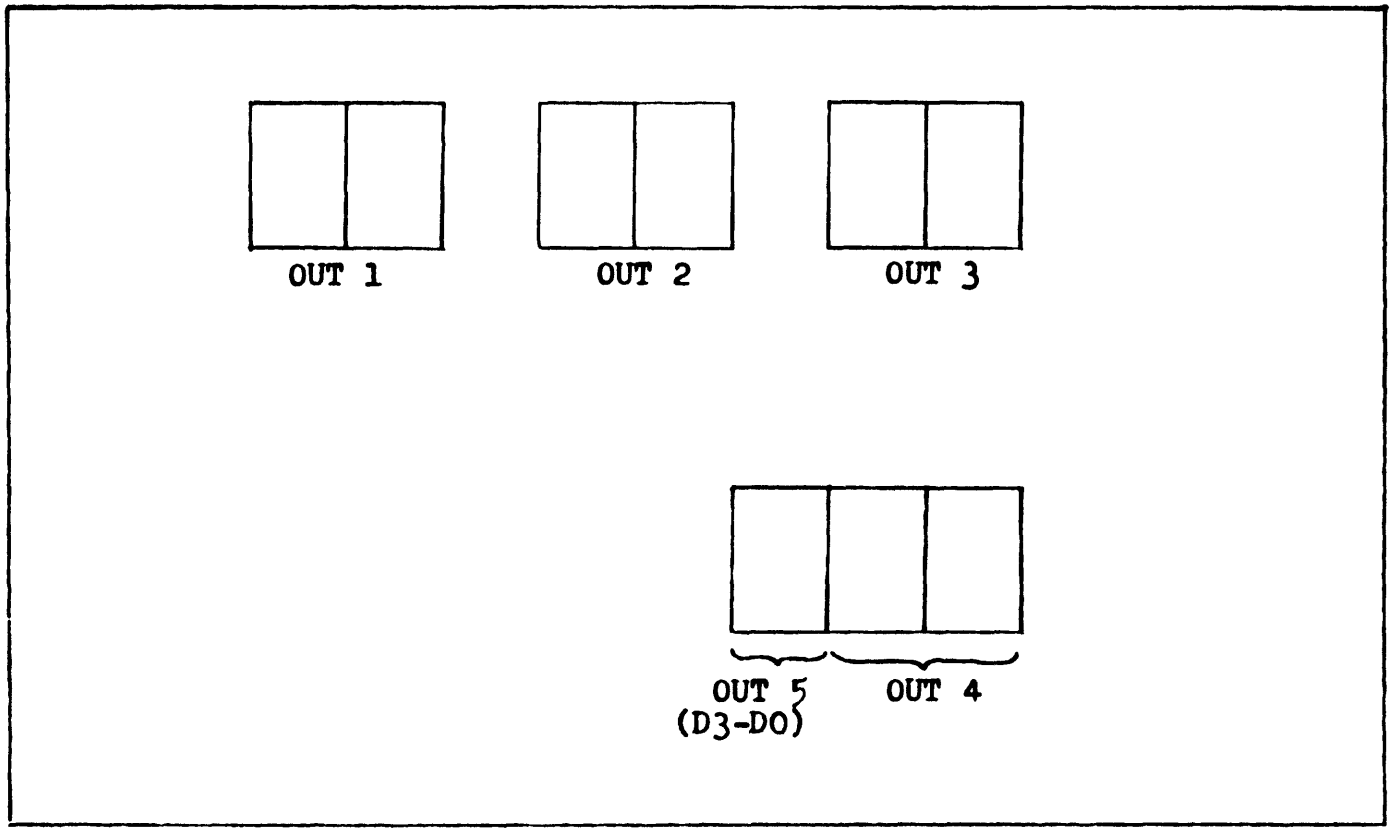

Figure 8

Locations of Display Output Ports on
the Front Panel

Keypad Module. The keypad module provides two kinds of inputs to the microcomputer: (1) a 16-key encoder allows parallel data input with a hexadecimal keypad and (2) closures of the "H", "L", and and "SHIFT" keys are debounced and connected to three input flags of the microprocessor. The INP 3 instruction reads the eight bits of data created by two successive key strokes on the hexadecimal keypad. The "H", "L", and "SHIFT" keys are connected to the $\overline{EF1}$, $\overline{EF2}$, and $\overline{EF4}$ input flags, respectively.

Serial-Output Module. The serial-output module consists of a transistor circuit which shifts voltage levels of the microprocessor's output flag, Q, in accordance with the EIA RS-232 standard for serial communication. The parallel-to-serial conversion of the output is done with software, eliminating the need for a UART (Universal Asynchronous Receiver and Transmitter) integrated circuit.

POWER AND PANEL CONNECTIONS

This section describes the elements of the data logger that are not plugged into the bus. The locations of these elements and their interconnection are shown.

Front Panel. Hexadecimal thumbwheel switches HS1 and HS2, and rotory switches RS1 and RS2 (Fig.2) are connected to input ports on the switch-input module (rotory switches RS1 and RS2 are not used in the present configuration). The RESET button and MODE switch are connected to the control module.

The keypad, keypad display, RUN button, and RUN and TRANSMIT lights are all connected to the keypad module. Circuitry for the keypad display is mounted on the back of the front panel (a circuit diagram is in the Appendix).

Table 5

Rotary and Hexadecimal Switch
Input Ports

Switch	input instruction	data bits
RS1 (9 position rotary switch)	INP 1	D3-D0
RS2 (5 position rotary switch)	INP 1	D7-D4
HS1 (hexadecimal switch)	INP 6	D7-D0
HS2 (hexadecimal switch)	INP 7	D7-D0

The HR, MIN, SEC, and DATA display LED's are mounted on the display module, located directly behind the front panel.

The POWER switch connects the hot AC line to the two power supplies.

Power Supplies. A line-operated +5V, 2 ampere power module (UPM-5/2000, Datel Systems, Inc., Mansfield, MA.) powers the displays and all of the digital hardware. A line-operated +15V, 200 milliampere power module (Md 920, Analog Devices, Norwood, MA.) powers the analog circuitry. One 1/2 ampere slow-blow line fuse is used for both supplies.

Interconnections. A terminal strip is used for all power connections and connections between modules which are not on the bus. Table 6 and Fig.9 describe the terminal connections. Wires labled 1 thru 8 correspond to terminals labled T1 thru T8. Figures 10 and 11 show the locations of the power modules and the terminal strip.

Table 6

Terminal Connections

Terminal	Signal name	Connections
T1	ANALOG IN	multiplexer module to A/D module
T2	REF OUT	A/D module to multiplexer module
T3	+15 V	power module to A/D module and multiplexer module
T4	VBAT (+5V)	power module to bus pin D
T5	COMMON	power module, bus pins 22 and Z, data cable
T6	-15 V	power module to A/D module, multiplexer module, and serial output module
T7	AC HOT	AC line to power modules
T8	AC NEUTRAL	AC line to power modules
(chassis)	AC GROUND	AC line to chassis

SOFTWARE CONFIGURATION

The program used in the data logger is described in this section. An overview of the entire program is presented first, followed by a more detailed description of the main routines within the program. A list of programs and subroutines, a map of RAM storage, a table of I/O ports, and a complete program listing is in the Appendix.

A flow chart of the program is shown in Fig.12. Program execution begins at memory address 0000 after a RESET. Four types of RESETs are possible: (1) a "power on RESET", (2) a manual RESET from a push button on the front panel, (3) a program controlled INTERNAL RESET, and (4) a RESET from the insertion of the $\overline{CLR}$ signal (see Fig.4). After a RESET, interrupts are disabled and initialization takes place. Initialization consists Bf setting up various program counters, stack pointers, and data-memory pointers. After initialization the MODE switch (front panel) is read, resulting in a conditional branch to the LOG routine or MONITOR routine.

LOG ROUTINE

The LOG routine is executed when the LOG mode is selected by the front-panel switch. This routine samples data every five seconds and displays one of the 16-channels selected by the keypad. Data are transmitted over the serial-output port at regular time intervals determined by a panel switch.

At the start of the LOG routine, a flag (INTF) is reset to "0" and interrupts are enabled (refer to Fig.12). The LOG routine then waits for an interrupt to be serviced by polling

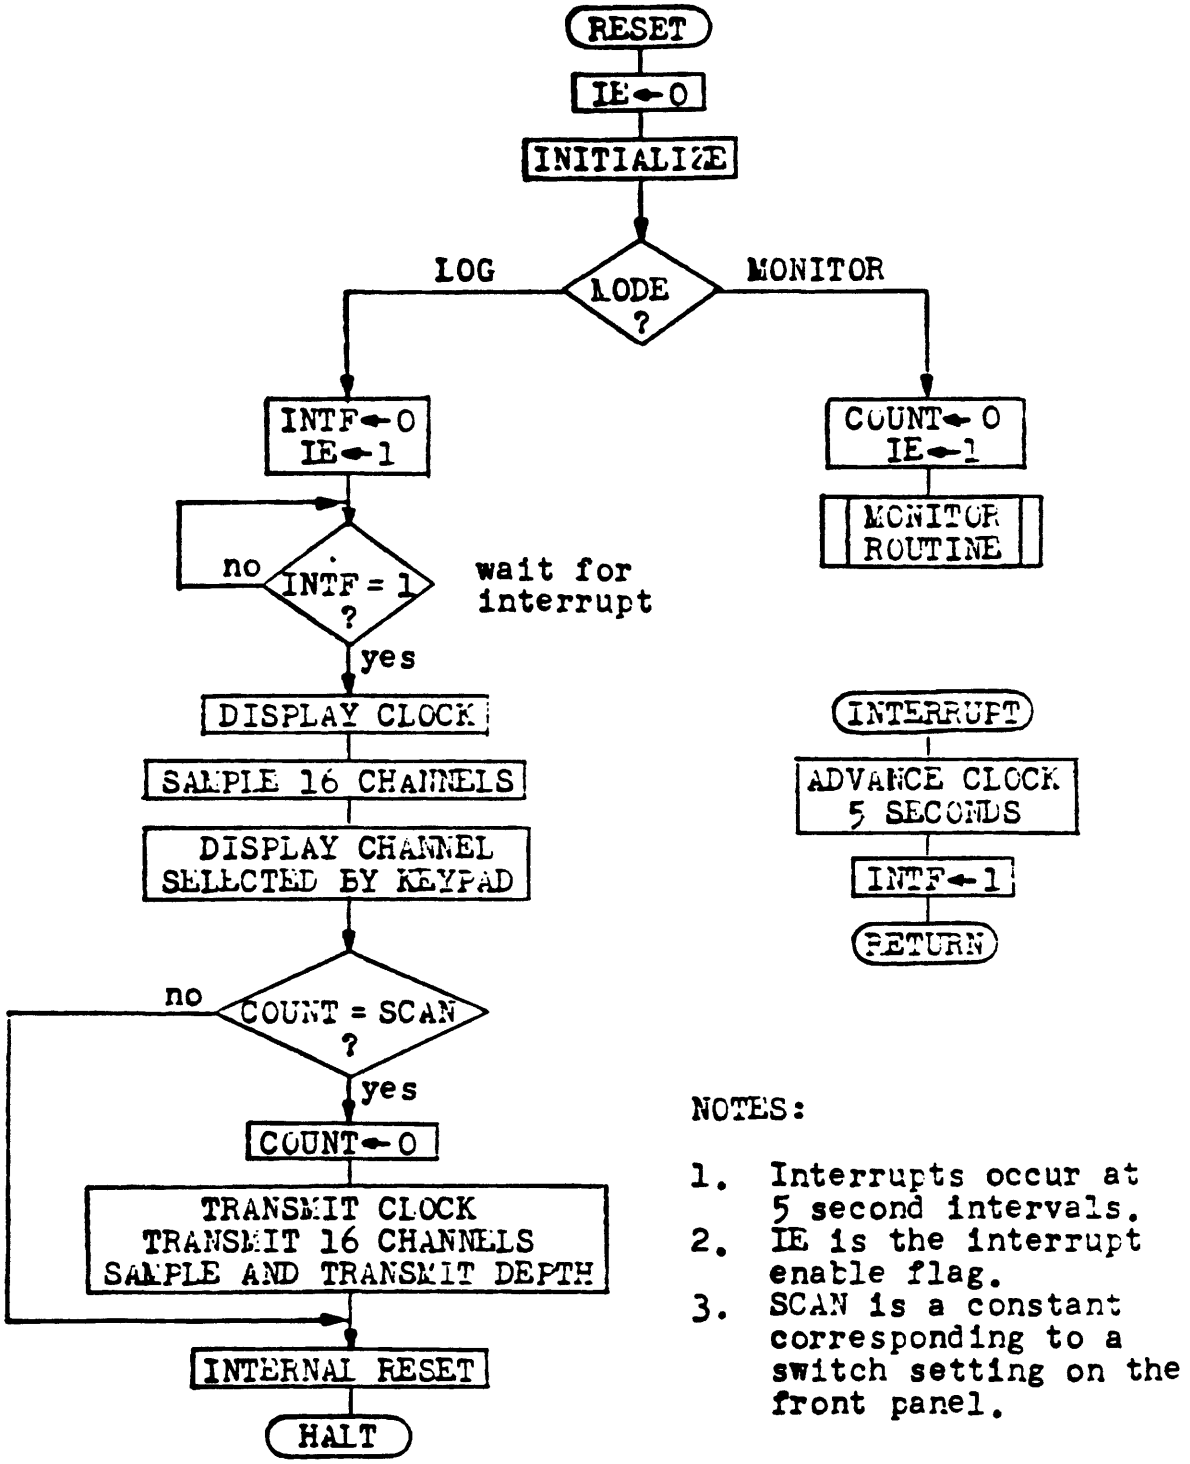

Figure 12

Program Flow Chart

the INTF flag (the interrupt-service routine sets this flag to "1"). The real-time clock, which is updated by the interrupt-service routine is then displayed on the front panel. Next, 16 channels with analog data are sampled and stored in memory. One of these 16 channels is selected by the least-significant hexadecimal digit in the keypad register for display on the front panel.

The constant, SCAN, determines the scan interval. When COUNT (which is incremented every five seconds) equals SCAN, the scan interval has elapsed and data are transmitted over the serial interface. Data transmission begins after clearing COUNT. The real-time clock data are transmitted first, followed by the data from the 16 analog channels. Next, the depth is sampled and transmitted.

The LOG routine terminates with the execution of the OUT 5 instruction, which causes an INTERNAL RESET. At the start of the next five-second cycle, the control module puts the CPU back into the RUN mode ($\overline{\text{EXT CLEAR}}$ =1) and execution starts again at location 0000. This cycle repeats as long as the data logger is in the LOG mode.

MONITOR ROUTINE

The MONITOR routine is used to start the execution of a program at any address, load data into RAM, and inspect any memory location. This routine is typically used to enter and execute test programs.

Interrupts are enabled and COUNT is initialized prior to execution of the MONITOR routine (see Fig.12). The MONITOR

routine can be re-entered by pressing the RESET button (while the data logger is still in the MONITOR mode).

INITIALIZATION

Initialization takes place after each RESET, which occurs every five seconds. The program resets itself after each LOG cycle with an INTERNAL RESET. If the program fails to assert this INTERNAL RESET due to an error in execution, the $\overline{CLR}$ signal on the control module will force the microcomputer into the RESET mode at the start of the next five-second cycle. This "guaranteed" RESET followed by initialization prevents the microcomputer from being "hung" in a loop or halted indefinitely.

Not all variables can be initialized in the MONITOR mode, however, the real-time clock must be set in the MONITOR mode.

The software makes use of the Standard Call and Return Technique (SCRT) for handling subroutines (see RCA CDP1802 Microprocessor Manual).

The CPU registers are used as memory pointers. Register R(1) contains the address of the interrupt-service routine. Register R(2) points to a free memory area for use as a stack. Register R(3) is used as the program counter for the main program and subroutines. Registers R(7) and R(8), and R(9) point to scratch-pad storage locations used by the MONITOR program.

INTERRUPTS

The interrupt-service routine is used to advance the real-time clock. The control module issues an interrupt to the CPU every five seconds. The interrupt routine updates the clock by adding five seconds to a count of hours, minutes, and seconds

in memory. These numbers are stored in hexadecimal form. The numbers are converted to decimal for display on the front panel for transmission over the serial interface.

The clock functions in both the MONITOR and LOG modes. The clock can be set in the MONITOR mode with a utility program (see operating instructions in Appendix).

Interrupts are disabled during initialization, because part of the initialization involves setting up the interrupt-service routine.

SERIAL OUTPUT PROGRAMMING

Data gathered by the data logger are transmitted to the tape recorder via the RS-232 serial interface. The Q output flag of the microprocessor is switched to either of two stable states at a given time, under program control, to provide the appropriate ASCII-coded data. A programmed delay in the software determines the transmission rate. Any rate up to 1200 BAUD is possible with the present software.

OBTAINING DEPTH DATA

The depth module converts serial data from the fathometer to a 16-bit parallel word. The word is read one byte (8 bits) at a time. Because the depth sounder and data logger operate asynchronously, the logger may read the 16 bits as they are being shifted into the register, resulting in an erroneous reading. This problem is overcome by performing multiple reads. The data logger reads the two bytes, delays for a short time, and then reads the two bytes again. If these two pairs of bytes do not form the same 16-bit word, two more bytes are read until two

consecutive pairs of bytes form the same word. When two consecutive pairs of bytes compare, the 16-bit word formed by either pair is taken as a valid reading.

RECOMMENDATIONS

We have constructed a more-compact battery powered version of the data logger, which consumes much less power. This allows the logger to be used in remote self-contained units, such as bouys. The keypad and display circuits, which are not necessary in the logging mode and the LED (light emitting diode) displays, which are the major power consumers, are now in a separated module that is connected to the CPU module through the 44-pin bus only when the system is started up or when testing in the monitor mode. An integrated circuit voltage inverter (ICL7660CPA, Intersil, Cupertino, CA.) provides the negative power to the operational amplifiers, allowing the system to be operated from a single 12VDC power source. Hardware modifications that lower the power consumption are: 1) the logic +5 volt power is strobed (off) to the CPU module (except to the 256 bytes of RAM; Fig.33) and 2) a lower-power analog to digital converter with an extremely low quiescent power consumption in the interrupt power mode (ADC-HC12B, Datel Inc., Mansfield, MA.) replaces the model ADC-HX12B.

ACKNOWLEDGEMENT

Special thanks is given to Laurence E. Schemel for assisting in the preparation and review of this report.

APPENDIX

TABLES

FIGURES

- LOGGING DATA (In Present Configuration) -

1. Set MODE switch to MONITOR.
2. Wait for "03 00 30" to appear on the panel display. This is the starting address and data of the program SET, which is for setting the real-time clock.
3. Press the "RUN" switch.
4. Press the "H" key for fast advance. Press the "L" key for slow advance. Press the "SHIFT" key for single (5 second) advance.
5. Switch to the LOG mode to start logging data.
6. Select scan interval by hexadecimal switch HS2. Scan interval = HS2 setting x 5 seconds.

- ENTERING AND EXECUTING TEST PROGRAMS -

1. Set MODE switch to MONITOR.
2. Select the high address (HI ADDR) by pressing any two keys (0-F) on the keypad. While pressing the "SHIFT" key down, press and release the "H" key.
3. Select the low address (LO ADDR) by

pressing any two keys (0-F) on the keypad. While pressing the "SHIFT" key down, press and release the "L" key.

4. To increment the address by one, press the "L" key. The corresponding data will appear in the SEC/DATA display.
5. To store the data on the keypad register (keypad display), press the "H" key. The data will be stored at the current address, and the address will be incremented by one.
6. To execute a program, select the programs starting address (HI ADDR) and (LO ADDR), and press the "RUN" switch.

GLOSSARY

Bus - A number of conductors used for transmitting signals or power from sources to destinations.

Byte - One piece of 8-bit parallel binary information.

Control bus - Control lines for special signals generated and sent out by the microprocessor.

CPU - (Central Processing Unit): That part of a microcomputer that controls the interpretation and execution of instructions.

Data bus - Eight separate lines connected to the 8-bit microprocessor which can transfer data to or from memory and input/output (I/O) ports.

EPROM - A form of ROM which is erasable and electrically reprogramable.

I/O port - A connection to a CPU which is configured (or programmed) to provide an input or output data path between the CPU and external devices, such as keypad, display, etc.

Memory-address lines - Input lines (A0-A7) to memory integrated-circuit chips from the microprocessor, that are used to select the memory word that is being written or read.

RAM - Random-access read/write memory integrated-circuit chip. Data stored in RAM is lost when power is turned off.

Registers - A fast-access circuit used to store words in a microprocessor.

ROM - Read-only memory, where software instructions are permanently contained during manufacturing of the integrated-circuit chip.

Table 7

List of Programs and Subroutines

Address HI	Address LO	Name	Description
00	00-39	RESET	Start of initialization.
00	40-85	MON	Monitor program.
01	00-0E	LOG	Calling program for LOG mode.
02	00-3B		Hexadecimal to decimal look-up table.
03	00-50	SET	Subroutine to set the real-time clock.
04	00-1C	ENTRY	Routine to initialize registers R1, R2, R3, R4, and R5 for SCRT.
04	27-58	B1200	Subroutine for the serial transmission of the byte in M(R(7)).
04	60-69	WAIT	Subroutine to wait for INTF = 1 (wait for interrupt).
04	70-7D	CLOCK	Subroutine to display the real-time clock.
04	90-BB	SAMPLE	Subroutine to sample the 16 analog channels and store in RAM.
04	D0-D7	DELAY1	80 microsecond delay.
04	D8-DF	DELAY2	7 millisecond delay.
04	E0-F7	ANIBBLE	Subroutine to convert the low 4 bits of M(R(7)) to ASCII and send.
05	00-0F	ABYTE	Subroutine to convert the two hexadecimal digits in M(R(7)) to ASCII and send.
05	18-24	SP	Subroutine to send ASCII space.
05	25-37	CRLF	Subroutine to send ASCII carriage return and line feed.
05	40-57	DISPLAY	Subroutine to display the channel selected by the keypad.
05	60-71	TXCLOCK	Subroutine to send the real-time clock data.
05	78-9B	TXDATA	Subroutine to send the data stored by SAMPLE.
05	B0-CE	TRANS	Subroutine to transmit data if COUNT = SCAN.
06	00-30	TXDEPTH	Subroutine to sample depth and send.
06	40-5D	CC	Subroutine to convert hexadecimal clock data to decimal.
07	00-2E	INTRPT	Interrupt-service routine. (code starts at 0700, entry point is 0701)
07	B0-DE	PDUMP	Program to dump the contents of the EPROM.

Table 8

Map of RAM Storage

Address HI LO	Name	Description
8C 00		Beginning address of RAM.
8C A0	LDAT(0)	Low 8 bits (D7-D0) of channel 0.
8C A1	LDAT(1)	Low 8 bits of channel 1.
.	.	.
.	.	.
.	.	.
8C AF	LDAT(F)	Low 8 bits of channel F (15).
8C B0	HDAT(0)	High 4 bits (D11-D8) of channel 0.
8C B1	HDAT(1)	High 4 bits of channel 1.
.	.	.
.	.	.
.	.	.
8C BF	HDAT(F)	High 4 bits of channel F (15).
8C C0	INTF	Flag set by interrupt-service routine.
8C C1	COUNT	Counts number of samples taken.
8C F0	BYTE0	Low byte from depth sounder.
8C F1	BYTE1	High byte from depth sounder.
8C FA	T0	Hexadecimal hours.
8C FB	T1	Hexadecimal minutes.
8C FC	T2	Hexadecimal seconds.
8C FD	HR	Decimal hours.
8C FE	MIN	Decimal minutes.
8C FF	SEC	Decimal seconds.
8C FF		Ending address of RAM.

Table 9

Table of I/O Ports

Instruction	Location of I/O port	Action
OUT 1	display module	D7-D0 → HR/HI ADDR display.
OUT 2	display module	D7-D0 → MIN/LO ADDR display.
OUT 3	display module	D7-D0 → SEC/DATA display.
OUT 4	display module	D7-D0 → low 8 bits of DATA display.
OUT 5	display module	D3-D0 → high 4 bits of DATA display.
	multiplexer module	D7-D4 → multiplexer address latch.
OUT 6	control module	trigger INTERNAL RESET.
OUT 7	A/D module	trigger A/D conversion.
INP 1	switch input module	encoded switch position (RS1) → D3-D0.
		encoded switch position (RS2) → D7-D4.
INP 2	control module	mode switch position → D0.
INP 3	keypad module	keypad shift register → D7-D0.
INP 4	A/D module	4 high bits of A/D conversion → D3-D0.
INP 5	A/D module	8 low bits of A/D conversion → D7-D0.
INP 6	switch input module	hexadecimal switch (HS1) → D7-D0.
INP 7	switch input module	hexadecimal switch (HS2) → D7-D0.
