POLYGON - Program Listing

BY

B. A. CHUCHEL¹

¹U.S. Geological Survey, Menlo Park, CA

INTRODUCTION

This report contains a listing of the FORTRAN program POLYGON. The Open-File Report #85-233-A [Chuchel, 1985] describes in detail how to use the POLYGON program. POLYGON features color-graphics, an interactive user dialogue, brief help messages, and "zooming" to selected portions of the terminal screen in order to edit and manipulate polygons using a graphics cursor or the Envision mouse. POLYGON has been developed in support of the U. S. Geological Survey's effort to characterize potential radioactive waste storage sites at the Nevada Test Site for the Nevada Waste Storage Investigations project.

POLYGON is a computer program for developing polygonal models on an Envision color-graphics terminal. The term "polygonal model" means (1) the coordinates of the corners of a set of polygonal shapes, (2) a set of parameters and parameter descriptions attached to each polygon, and (3) the topologic structure that links the polygons in a storage hierarchy. POLYGON uses a data structure called a quadruply linked tree [Knuth, 1969, p. 352] to store the topology of the collection of polygons composing the model.

These polygonal shapes may subsequently be used by independent modeling programs to represent three-dimensional shapes of gravitational or magnetic sources; for example, output from POLYGON is directly compatible with programs MAGPOLY or GRAVPOLY [Plouff, 1975a, 1975b; Godson 1983a, 1983b] and PFGRAV3D or PFMAG3D [Blakely, 1981].

A model may consist of up to 100 polygons; each with up to 100 vertices. Each polygon may be assigned up to ten numerical parameters, each with a descriptive label. A polygon's sides may not be self-crossing; perimeters of polygons are not allowed to cross, but any number of polygons can be completely contained within other polygons.

POLYGON is written in DEC (Digital Equipment Corporation) extended FORTRAN 77 and is presently operational on the USGS, Branch of Geophysics, VAX/VMS computer. The program is written to operate on the Envision 200 series of color-graphics terminals by Envision Technology Incorporated. The 200 series features a Tektronix 4014 compatible instruction set [Envision, 1983]. Modular construction of the program should make it relatively simple to convert to other color-graphics terminals.

```

C+ *****
C Program POLYGON is designed to facilitate the construction
C and editing of the geometries of polygons interactively
C on an Envision color graphics terminal.
C
C Various output files may be generated: for example, output
C files compatible with the programs GRAVPOLY [Godson, 1983b]
C and MAGPOLY [Godson, 1983a] may be created. A standard
C grid file may also be created which is compatible with the
C programs PFGRAV3D and PFMAG3D [Blakely, 1981].
C
C POLYGON can take input from the Envision mouse or the cursor
C control keys on the numeric keypad. For detailed information
C about using the program see the USGS Open-File report #85-283-A
C "POLYGON - An Interactive Program For Constructing and Edit-
C ing the Geometries of Polygons Using A Color Graphics Terminal".

C tangle - Turning ANGLE
C- *****
      PURPOSE.
      Determines the turning angle (relative heading change)
      THETAD in degrees when going from the line segment
      (x1,y1)-(x2,y2) to the line segment (x2,y2)-(x3,y3).

      Using the equation:
          c**2=a**2+b**2-2.*a*b*cos(alpha)
      where a,b are the distances from the corner (x1,y1),

```

```

C      (x2,y2) and (x2,y2), (x3,y3) respectively; and the
C      turning angle is defined as:
C      thetad=180.*theta
C
C      FORM.
C      Call tangle(thetad,x1,y1,x2,y2,x3,y3)
C
C      PARAMETERS.
C      THETAD - Turning angle in degrees.
C      (x1,y1),(x2,y2),(x3,y3) - End points of line segments.
C
C      NOTE: The THETAD returned is a positive number between 0.*theta
C      and 180.*theta degrees; TANGLE does not make a distinction
C      between a left or right turn.

C      Walk - Starting at the position of polygon NGON in the tree
C              (topology array), WALK returns the node position of the
C              next polygon in the tree. The walk proceeds as follows:
C
C              (1) Move down the (sub)tree on the 'left' side, by
C                  looking at idown of the current position. If this
C                  is not zero return this as the next polygon.
C
C              (2) When a polygon is not found 'below' the current
C                  position (idown is zero), look to the right of
C                  this position and test:
C
C                  (a) If a polygon is found on the right, return
C                      this polygon.
C                  (b) If a polygon is not found on the right, move
C                      up a level and reapply test (a).
C
C              (3) When no more polygons are found to the right and
C                  above the current position, the tree has been
C                  completely searched.
C
C      Variables:
C
C      next = Next polygon in tree
C      >0 = a polygon exists
C      0 = tree has been exhausted
C
C      ngon = Position in tree where walk is to start
C              (ngon must be greater than zero).
C
C

```

```

C      itest = Error flag
