ABSTRACT

Cylindrical (axisymmetric) flow to a well is an important specialized topic of ground-water hydraulics and has been applied by many investigators to determine aquifer properties and determine heads and flows in the vicinity of the well. A recent modification to the U.S. Geological Survey Modular Three-Dimensional Finite-Difference Ground-Water Flow Model provides the opportunity to simulate axisymmetric flow to a well. The theory involves the conceptualization of a system of concentric shells that are capable of reproducing the large variations in gradient in the vicinity of the well by decreasing their area in the direction of the well. The computer program documented in this report serves as a preprocessor to the U.S. Geological Survey model by creating the input data file needed to implement the axisymmetric conceptualization. This report contains a listing of the computer code, a disk containing the computer code, and a description of the data input requirements to this preprocessor.

INTRODUCTION

The original U.S. Geological Survey (USGS) Modular Ground-Water Flow Model (McDonald and Harbaugh, 1988), known as MODFLOW, assumed that model nodes are in the center of rectangular cells and that transmissivity is constant within a cell. Based on these assumptions, the model calculates coefficients, called conductance, that are multiplied by head difference to determine flow between cells. A generalized finite-difference capability was developed for the USGS model (Harbaugh, 1992) to allow the model program to read conductance as input instead of calculating it internally under the assumption of block-centered finite-difference discretization.

This generalized finite-difference capability allows the conductances to be calculated externally using a node-centered radial discretization (as described in Bennett and others, 1990; and Reilly and Harbaugh, 1993) for input to the flow model. This report documents a preprocessor computer program that calculates conductances and storage capacities for a radial axisymmetric node-cen-

tered finite-difference grid. The calculated conductances and storage capacities can then be included as the input to MODFLOW to simulate axisymmetric flow to a well.

COMPUTER PROGRAM

The theory and logic of the computer program are described in Reilly and Harbaugh (1993), along with an example of the use of the preprocessor. A listing of the computer program used in Reilly and Harbaugh (1993) is provided in this document to make the program available and to provide a record of the original program. An MS-DOS[1] compatable, 1.2 megabyte diskette that contains the computer readable text files is included with this report .

The files three files contained on the diskette are: 1. RAD_MOD.FOR, 2. RAD_MOD.TXT, and 3. NEUMAN.DAT. These computer readable files are listed in the three appendixes. Appendix 1 is a listing of the file RAD_MOD.FOR which is the Fortran source code of the preprocessor contained on the diskette. Appendix 2 is a listing of the file RAD_MOD.TXT which provides the input instructions for the input to the program as described in Reilly and Harbaugh (1993). Appendix 3 is a listing of the file NEUMAN.DAT which is the input data set used in the sample problem described in Reilly and Harbaugh (1993).

INPUT TO PROGRAM:

Data set 1:

ALPHA,RW,NCOL,NROW,LOCAT

Format (2F10.0,3I5)

Data set 2 (one record for each layer in the model):

IR,DELZ(IR),KR(IR),KZ(IR),SS(IR)

Format (I5,4F10.0)

Where:

ALPHA=R(I+1)/R(I), This is the ratio of the lateral distance between neighboring nodes {usually between 1.1 and 2.0},

RW=Radius of the well

NCOL=Number of nodes laterally (variable NCOL in MODFLOW) {must be greater than 4 and is usually greater than 15}

NROW=Number of layers (variable NROW in MODFLOW)

LOCAT = Unit number for reading GFD data in MODFLOW

IR=Layer number

DELZ=Thickness of layer IR

KR=Radial hydraulic conductivity in layer IR

KZ=Vertical hydraulic conductivity in layer IR

SS=Specific storage of material in layer IR (L^{-1}), can be set to S_y/DELZ for the top layer to represent the water table, where S_y is the specific yield (dimensionless).

Note: The output from this program is all of the required input data for the General Finite-Difference Package (GFD). The value for IGFDCB (Harbaugh, 1992, p.13) is specified as zero. This can be changed, if desired, with an editor after the GFD data file has been created by the preprocessor.
