Worldwide Asbestos Supply and Consumption Trends from 1900 to 2000

**By Robert L. Virta
U.S. Geological Survey
Reston, VA**

Abstract

The use of asbestos is one of the most controversial issues surrounding the industrial minerals industry. Its carcinogenic nature, an overall lack of knowledge of minimum safe exposure levels, its widespread use for more than 100 years, and the long latency for the development of lung cancer and mesothelioma are the main contributing factors to these controversies. Another factor is that, despite decades of research, the mechanisms responsible for its carcinogenic properties are still largely unknown. The United States has produced about 3.28 million metric tons of asbestos fiber and used approximately 31.5 million tons between 1900 and 2000. About half of this amount was used since 1960. Cumulative world production during that same time period was about 173 million tons. Assuming that unusually large stocks are not maintained and that world consumption roughly equals production, about half of the world production and consumption occurred since 1976. The United States and western European nations were the largest consumers of asbestos during the first two-thirds of the 20th century. They were surpassed by the collective production and consumption of States within the former Soviet Union by the 1970s. With the onset of the health issues concerning asbestos in the late 1960s and early 1970s, world production and consumption began to decline during the 1980s. In 2000, world consumption, estimated to be 1.48 million tons, was only 31% that of 1980. Countries in Asia, South America, and the former Soviet Union remain the largest users of asbestos. More specifically, Brazil, China, India, Japan, Russia, and Thailand are the only countries that consumed more than 60,000 tons of asbestos in 2000. These six countries accounted for more than 80% of world's apparent consumption in 2000.

1. INTRODUCTION

Asbestos has been used for more than 3000 years. Early evidence of its use to strengthen clay pottery as long ago as 2500 B.C. has been found in Finland (Gross and Braun, 1984, p. 9). Anecdotal stories of its use have been reported by many including Pliny the Elder (circa 79) and Marco Polo (circa 1250). Some of the earlier uses were crematory shrouds, lamp wicks, and incombustible napkins and tablecloths. The tablecloths could be tossed in the fire to be cleaned without fear of damage. Ben Franklin reportedly used an asbestos purse not to protect his money, but to prevent it from burning the proverbial hole in his pocket (Alleman and Mossman, 1997, p. 70-71; Anonymous, 1928, p. 14-16; Bowles, 1937, p. 5-7; Bowles, 1946, p. 13-14; Natural Resources Board of Southern Rhodesia, 1963, p. 14; Selikoff and Lee, 1978, p. 6-7; Sinclair, 1959, p. 1-3).

The beginnings of the modern asbestos industry began in the early 1800s when the Italians established a textile manufacturing industry. Products such as fabrics, string, and book covers were made partly with asbestos (Alleman and Mossman, 1997, p. 71; Bowles, 1946, p. 14; Sinclair, 1959, p. 3, 277). Consumption at that stage still was extremely low compared with 20th century usage. As nations became more industrialized, new uses that took advantage of the strength, heat resistance, and flexibility of asbestos fibers began to appear by the mid-1800s. Asbestos soon was used in packings in steam glands of high-temperature machines, insulation on steam pipes, and fireproof paint and roofing materials. Textiles still provided a ready, yet small market, during this period of expanded use (Alleman and Mossman, 1997, p. 72; Sinclair, 1959, p. 278).

The discovery and opening of large asbestos deposits in Canada, Russia (collectively grouped with the other States of the former Soviet Union and henceforth referred to as the FSU unless specified), and South Africa in the late 1800s overcame the problem of providing a large and steady supply of asbestos to meet growing demand (Selikoff and Lee, 1978, p. 8; Sinclair, 1959, p. 3). The development of the Hatschek machine for making asbestos-cement flat and corrugated panels in 1900 resulted in a significant increase in demand for asbestos (Rosato, 1959, p. 63; Sinclair, 1959, p. 279). This technology enabled the mass production of inexpensive, fireproof building materials. Soon to follow was the development of a method to mass produce asbestos-cement pipe in 1929, which proved invaluable for the construction of municipal water supply and waste lines (Rosato, 1959, p. 79). The rise of the automobile industry in the early 1900s brought about an ever-increasing demand for asbestos to manufacture brakes, clutch components, and engine gaskets (Sinclair, 1959, p. 278).

With the growth of the world economies and population after World War I and the Great Depression of the 1930s, there was growth in construction and other market sectors. Sales and use of asbestos increased to meet the demands of these new and expanding markets. In addition to automotive and asbestos-cement products, demand grew for asbestos millboard and paper for electrical panels; textiles for insulating electrical wiring; spray-on asbestos products for protecting steel girders in buildings; reinforcing, heat-resistant fillers for plastics; fire-resistant roofing materials such as asbestos felts, shingles, and asphalt roofing compounds; inexpensive, durable, and dimensionally stable flooring products such as vinyl asbestos tile and flooring felts; heat- and acid-resistant gaskets and packings; thermal insulation on boiler systems for buildings and homes; fireproof suits for firefighters; reinforcement for plasters and caulking compounds; and filler and reinforcer in paints and asphalt road surfacing (Rosato, 1959, p. 23-27; Selikoff and Lee, 1978, p. 19-20). In all, asbestos was used in about 3,000 applications or product types by 1958 (Quebec Asbestos Information Service, 1959, unpaginated). A time line listing significant developments in the early history of the asbestos industry was published in 1953 (Anonymous, 1953, p. 4-6). Selikoff and Lee (1978, p. 17-18) also presented a historical time line of significant events regarding the development of the asbestos industry through 1972. Several of these developments are listed in Table 1. Over time, asbestos has been honored for its “service to humanity” (Alleman and Mossman, 1997, p. 72) and called a “boon to humanity” and “faithful servant of mankind” (Bowles, 1946, p. 6, 37), “the most important of the non-metallic mineral products of the world—and certainly one of the most wonderful” (Summers, 1919, p. 10), and even the “magic mineral” (Quebec Asbestos Information Service, 1959, unpaginated).

For much of the 20th century, the United States was the leading user of asbestos (Buckingham and Virta, 2002; Ross and Virta, 2001, p. 84-85; Appendix A). This occurred because much of the early manufacturing research was conducted in the United States, industrial demand for asbestos grew rapidly in the early 1900s, and a ready supply of asbestos just across the border in Canada (Sinclair, 1959, p. 279). In the United States and, to a lesser extent, in many European countries, the bubble burst on asbestos’ popularity in the late 1960s and early 1970s (Alleman and Mossman, 1997, p. 74). While health research from the 1920s to 1940s demonstrated an association between exposure to asbestos and asbestosis, it wasn’t until the late 1950s and early 1960s that an association between asbestos exposure and lung cancer was conclusively demonstrated (Gross and Braun, 1984, p. 20-21; Selikoff and Lee, 1978, p. 22-23, 31-32; U.S. Department of Health and Human Services, 1992, p. 289-290). With these findings, public opposition to the use of asbestos increased significantly. Liability eventually became a major issue for producers and manufacturers. In the United States, asbestos producers and manufacturers of asbestos products began facing an increasing number of large class action lawsuits filed on behalf of those suffering from asbestos-related diseases (Virta, 2002, p. 15). This liability contributed to a shift by product manufacturers to asbestos substitutes, such as aramid fiber, cellulose fiber, polyvinyl alcohol fibers, or wollastonite or alternative products such as fiberglass shingles, mineral wool insulation, ductile iron and polyvinyl chloride pipe, graphite packings, metallic disk brake pads, and aluminum siding (Hodgson, 1989; Virta, 1994). Similar movements toward the use of non-asbestos products followed in many other countries, particularly in western Europe. It should be noted, however, that many industrial minerals followed a pattern of growth through the 1960s and 1970s and then, as markets matured, the rate of growth flattened or even declined. The effect of maturing asbestos markets probably was superimposed on top of the effects of the asbestos health issue in the United States and many European nations, exacerbating the situation for the industry.

These factors resulted in a dramatic decline in the use of asbestos in the industrialized countries, a movement toward increasingly strict exposure limits for occupational settings, new consumer and environmental regulations, and, by the early 2000s, full or partial bans on the use of asbestos in 16 countries, including Argentina, Austria, Belgium, Chile, Denmark, Finland, France, Germany, Italy, the Netherlands, Norway, Poland, Saudi Arabia, Sweden, Switzerland, and the United Kingdom. Additionally, the European Union has voted to phase out the use of asbestos, with exceptions, by 2005. However, some 60 countries still favor the controlled use approach regarding chrysotile asbestos (B.J. Pigg, Asbestos Information Association/North America, oral commun., 2002).

Of interest, from a historical and exposure standpoint, is how much asbestos was used in each country over time. This information provides a means by which to determine past, current, and future markets for asbestos and some insight as to the potential for past occupational asbestos exposures in various countries. Total and market specific usage data for asbestos generally are lacking because most countries did not have the resources or feel the need to gather and evaluate that kind of information. Even in the United States, only asbestos production (sales) has been tracked for more than 100 years; import data were not gathered until 1931 and asbestos consumption, by market, was not documented until about 1972, with only estimates extending back to 1965. This paper reviews production and market changes throughout the world and provides some insight as to the levels of asbestos used in individual countries over time.

2. ACKNOWLEDGMENTS

I would like to thank Ms. Linder Roberts, statistical assistant, U.S. Geological Survey (USGS), Minerals Information Team, for compiling the data from the British Geological Survey World Mineral Production reports that were used in the apparent consumption estimates. I would also like to thank Mr. Michael Potter, a fellow USGS mineral commodity specialist who has provided reviews of many of my reports; Dr. Greg Meeker, geologist with the USGS; Mr. Louis Perron, asbestos specialist with Natural Resources Canada; and Mr. B.J. Pigg, Asbestos Information Association/North America, for their reviews of this article.

3. DATA SOURCES

The data cited in this report were extracted from a variety of sources. This was necessary because no single source contains a complete set of all statistics used in this paper. These include the USGS Minerals Yearbook chapters on asbestos after 1995 (Vol. I, Metals and Minerals); the U.S. Bureau of Mines (USBM) Minerals Yearbook chapters on asbestos before 1996 (Vol. I, Metals and Minerals) and the corresponding International volumes of the Minerals Yearbooks between 1963 and the present; the Statistical Summary of the Mineral Industry published between 1923 and 1973 by the Institute of Geological Sciences, Mineral Resources Division, Her Majesty's Stationery Office, London; the World Mineral Statistics published between 1983 and 2001 by the British Geological Survey (BGS), Keyworth, Nottingham, England; the World Mineral Statistics published between 1981 and 1983 by the Institute of Geological Science, Natural Environment Research Council, Her Majesty's Stationery Office, London; the 1973, 1990, and 1999 Canadian Minerals Yearbooks, Natural Resources Canada (and its predecessor Energy, Mines, and Resources Canada); Internal Report No. 5 by the Department of Mines, Minerals Bureau, Braamfontein, Republic of South Africa, 1977; the 1988 and the 1998/1999 editions of the South Africa's Mineral Industry, by the Department of Minerals and Energy, Mineral Economics Directorate, Minerals Bureau, Pretoria, Republic of South Africa; and Griffiths, Joyce, 1989, South Africa's Minerals (p. 21), Industrial Minerals, no. 263, August, p. 18-53.

In general, data in publications have been revised as new data were received. These revisions, however, have not been published in any systematic fashion. As a result, data from the various sources frequently do not agree for any given year. Another problem is that data by country are often revised but not published; only the revised total world production data were published. Thus, the sum of production of individual countries may not equal the revised world production. Another problem is that the data are a mix of ore production, fiber production, and fiber sold or used. Also, data were not always available from all countries for all years. When estimates were made in publications, usually there was no indication which data were estimates nor any indications of how the estimates were made. There is no way to resolve these problems short of the impossible task of retrieving all of the survey data, so they will have to be accepted as a limitation of this historical review.

When possible, data were extracted from one source to maintain consistency over the longest period of time. For the section entitled "World supply and trade," data extracted from the USGS and USBM Minerals Yearbook chapters on asbestos were used as the basis for the evaluation. Some of the data are available on the USGS web site at URL <http://minerals.usgs.gov/minerals/pubs/of01-006/asbestos.html>. Some of the numbers under "World supply and trade" do not match those on the USGS web site because estimates for non-responding survey countries are included in this report. These estimates are based on world asbestos market conditions, accounts from other data sources, and long-term production trends within the country. Adjustments also were made for countries reporting crude ore production rather than fiber production. For the section "World consumption," data extracted from the publications of the BGS and its predecessors were used to calculate the apparent consumption for each country. When discrepancies arose or data were not available in the BGS publication, data extracted from the previously mentioned references or estimates that were the most consistent with market conditions at the time were used. Despite these caveats, the data are deemed sufficiently reliable to make a fairly accurate evaluation of asbestos consumption trends worldwide as well as those of regions and individual countries. The reader should note, however, that the tables presented in this report and appendices are snapshots of world activities at a particular

time. Activities that may have occurred during the time gaps are not taken into consideration. Also, data on some countries were not available in 1999 and 2000 so their absence in Appendix A tables does not necessarily mean that there was no asbestos production, exports, or imports for a particular country for a particular year.

4. WORLD SUPPLY, DEMAND, AND TRADE

4.1 United States

Supply

Commercial asbestos production was recorded in 15 States since 1900: Alaska, Arizona, California, Georgia, Maryland, Massachusetts, Montana, North Carolina, Oregon, Pennsylvania, South Carolina, South Dakota, Vermont, Virginia, and Wyoming. There probably were small amounts of unrecorded production in additional States. The largest producer States were Arizona, California, North Carolina, and Vermont. Most of the asbestos mined in the United States was chrysotile although much of the early production was of amphibole asbestos. These amphibole asbestos mines generally were short-lived. The longest sustained production of amphibole asbestos was from North Carolina, where anthophyllite asbestos was mined from the early 1930s to 1979 (Bowles, 1934, p. 2-7; Bowles, 1959, p. 6-7; U.S. Geological Survey and U.S. Bureau of Mines Minerals Yearbook chapters on asbestos, 1900 to 2000).

U.S. asbestos production was relatively low at the start of the 20th century, less than 10,000 tons per year until 1936. After the Great Depression of the early 1930s and with onset of World War II, U.S. production increased through 1942 to meet increased war demands. After 1942 and during the recessionary period following World War II, demand and consequently U.S. production declined, not reaching its former level for another six years. It wasn't until 1965 that the United States reached the 100,000 metric-ton-per-year production mark. World production, by 1965, had already exceeded 2.8 million tons. U.S. production exceeded 100,000 tons per year for only 10 years, 1965 to 1973 and in 1976. Peak production was about 136,000 tons in 1973, which was 3% of the world's asbestos production and only 17% of the U.S. demand for that year (table 2). It was at that stage that the asbestos health controversy began to seriously affect demand, causing U.S. production to stagnate and then take a precipitous decline. The production of 5,000 tons in 2001 was only 4% of the peak in 1973. In 2002, the last asbestos mine in the United States closed, marking the end of more than 110 years of U.S. asbestos production.

Despite having produced 3.28 million tons between 1900 and 2000, the United States almost always was dependent on imports to meet most of its demand. Imports have supplied more than 88% of the U.S. asbestos needs over the century. Only for 5 of the past 100 years has U.S. import dependence been less than 90%. Canada was the major supplier of asbestos to the United States throughout most of the century, averaging 94% from 1900 to 2000. The RSA supplied up to 6% of U.S. imports but averaged 4% since the 1930s (table 2). Swaziland and Zimbabwe were two other small, yet important, suppliers of asbestos to the United States.

About 97% of the 29.5 million tons of asbestos imported into the United States during the 20th century was chrysotile, mostly from Canada. Crocidolite imports were 365,000 tons (1.2% of total asbestos imports) and amosite imports were 282,000 tons (0.9% of total imports). The United States has not imported any amosite since 1985. Most of the asbestos imports that have been reported as crocidolite for the past 5 or so years are believed to be chrysotile based on its source and Customs value (table 2).

Demand

Asbestos consumption in the United States was minimal in the 1800s. At that stage, markets primarily were low technology applications such as textiles (i.e., fireproof cloth such as theater curtains, boots, gloves, etc.) and insulation and packings for steam locomotive and other boiler systems (Bowles, 1937, p. 8-10). Consumption did not increase significantly until the early 1900s when an expanding population and increased industrialization resulted in a demand for a steady supply of cost-effective, mass-produced construction materials. Asbestos products that filled these needs included asbestos-cement pipe and sheet, coatings and compounds, flooring, friction materials such as brakes and clutches, and insulation. These were the large tonnage uses for asbestos. Other smaller, but still important applications, were in asbestos paper, asphalt emulsions, packings and gaskets, plastics, roofing felts, shingles, and textiles (U.S. Bureau of Mines, 1985, p. 62-64).

Starting from a rather small 15-20,000 tons per year consumption around 1900, markets expanded to a peak of 801,000 tons in 1973. Demand after 1900 was fairly continuous with a short period of rapid growth in demand during World War I. The end of the Great Depression by the middle 1930s and the onset of World War II in the late 1930s brought about a brief surge in demand to meet U.S. demands. Demand dropped back to pre-war levels after the war and then increased in step with economic growth in the United States. There was a general flattening of the demand curve in the 1950s during the Korean conflict and later in the early 1970s. The flattening of demand occurred after the early 1970s because the use of asbestos was becoming controversial and markets for asbestos in the United States appear to have matured. After 1973, asbestos consumption declined rapidly. By 2000, consumption was only about 15,000 tons or 1.9% of 1973's level and equivalent to consumption in the late 1800s (table 2).

In relation to overall world consumption, the United States was the largest market economy and world user of asbestos during much of the 20th century. The U.S. consumed about 18% of the world's asbestos production between 1900 and 2000. This, in itself, is

remarkable considering that for the last 35 years of the 20th century, the U.S. share consistently has been less than 10% and it has been less than 1% for the past 12 years. Until 1950, the ratio of U.S. apparent consumption to world production was between 37% and 99%, averaging 62%. This clearly demonstrated the strength of the U.S. asbestos industry in its early history. As more countries developed asbestos manufacturing industries after World War II, the U.S. share of the world market declined, averaging only 14% from 1950 to 2000 (table 2).

Following World War II, demand for asbestos fiber increased at a faster rate in other parts of the world than in the United States. Much of this growth was spurred by the massive reconstruction efforts in Europe after the war and later by growing economies. Consumption in the United States declined from 51% of the world production in 1950 to 19% in 1970. With the onset of the asbestos health issues, U.S. consumption declined even further. By 1975, U.S. consumption was 13% of world production; by 1985, 4%; and by 2000, less than 1% (table 2).

More than 71% of the U.S. consumption of asbestos occurred between 1950 and 2000 and about 39% since 1965, which is the earliest available estimate of U.S. asbestos consumption, by market share. Thus, a fair idea of the markets into which a sizable share of the asbestos went throughout most of the history of U.S. asbestos usage can be determined. Table 3 presents the end use data for asbestos from 1965 to 2000 (U.S. Bureau of Mines Mineral Facts and Problems, 1975, p.113; 1980, p.63; 1985, p. 58; U.S. Bureau of Mines Minerals Yearbooks, 1984-2000). The totals in table 2 do not match exactly those of table 3 because of rounding of data and exclusion of entries of less than 1,000 tons in table 3. With that caveat, the average percent breakout of the major U.S. markets between 1965 and 2000 was asbestos-cement pipe, 18%; asbestos-cement sheet, 6%; coatings and compounds, 2%; electrical insulation, 2%; flooring, 22%; friction products, 11%; packing and gaskets, 4%; paper, 3%; plastics, less than 1%; roofing products, 12%; textiles, 2%; thermal insulation, less than 1%; and other, 18% (table 3).

Because of the asbestos health issue, markets changed over this time period (table 2). The largest losses were in asbestos-cement pipe and sheet, coatings and compounds, flooring, and insulation. In 1965, before the asbestos health issue intensified, flooring accounted for 25% market share, followed by asbestos-cement pipe (19%), roofing (9.9%), friction products (8.9%), asbestos-cement sheet (6.9%), electrical insulation and packing and gaskets (3% each), paper and textiles (2% each), coatings and compounds, thermal insulation, and plastics (less than 1% each) and unknown uses (20%). By 1980, consumption was 19.5% for flooring, followed by friction products (14.5%), asbestos-cement pipe (11.7%), roofing (6.7%), asbestos-cement sheet (6.4%), packing and gaskets (3.3%), coatings and compounds (3.1%), electrical insulation (1.7%), thermal insulation (0.8%), plastics and textiles (0.6% each), paper (0.3%), and unknown uses (30.9%). In 2000, the end use markets were roofing (60%), gaskets (20%), friction products (13.3%), coatings and compounds, plastics, and unknown uses (6.7%).

Some anecdotal information on markets prior to 1965 is available. Josephson and Marsh (1948, p. 146-147) reported that U.S. usage of asbestos fines in floor tile began to increase rapidly following the development of suitable production methods. A 1939 and 1947 U.S. Bureau of the Census report also illustrates the growth in the U.S. asbestos manufacturing industry. Production of asbestos floor tile increased to 34,681 million square meters (41,479 million square yards) in 1947 from just 4,124 million square meters (4,933 million square yards) in 1939, an 8-fold increase in as many years. Corrugated sheet production increased to 4,258 million square meters (45,839 million square feet) in 1947 from 698 million square meters (7,551 million square feet) in 1939. Less dramatic but still substantial increases are observed in many other product categories (Josephson and Barsigian, 1951a, p. 146). Kennedy and Foley (1960, p. 200) reported that 96% of the chrysotile used in the United States was short fiber, used principally in asbestos-cement and asbestos-asphalt building materials.

4.2 Canada

Chrysotile mining began in Canada around 1878 (Bowles and Barsigian, 1945, p. 1481; Sinclair, 1959, p. 3). By 1920, Canada already was producing about 162,000 tons per year or 84% of the world's production. Production suffered in the early 1930s because of the Great Depression in the United States (the largest Canadian market) and recessions worldwide that affected the entire asbestos industry. By 1935, the U.S. economic recovery bolstered the Canadian asbestos industry. The onset of World War II slowed production around 1940 but it recovered around 1946. During that time, mines and mill capacities in Canada were being increased rapidly to meet growing world demand (Josephson and Marsh, 1946, p. 150). Production was slowed briefly by a strike in the Canadian industry in 1949 (Josephson and Barsigian, 1951b, p. 145-146) but quickly resumed following resolution of the dispute. Despite the FSU emerging as a major asbestos producing nation, Canada still retained 62% of global production in 1950.

Competition arose as the FSU, Italy, the RSA, Swaziland, the United States, and Zimbabwe began to increase their production in the 1940s and 1950s, soon to be followed by China in the early 1960s and Brazil and Cyprus in the middle 1970s. By 1960, Canada's share of global production declined to 46% despite an increase in its production. Canadian production peaked in the 1970s, almost coinciding with the peak U.S. consumption as would be expected because the United States was the major destination for Canadian fiber. Then, in 1975, the Canadian asbestos producers suffered from a major mill fire, a landslide in a major mine, strikes, and political and transportation issues, resulting in a sharp (36%) decline in production (Northern Miner, 1975, p. B-12). The industry rebounded quickly, however, only to face the asbestos health issue, which began in the United States in the early 1970s and quickly spread to other countries. Two other factors affecting sales were declines in some of the world economies and political instability in some of the developing nations, which were important purchasers of Canadian fiber in the late 1970s (Roskill Information Services, 1983, p. 20). Canadian production declined through 2000 as asbestos markets worldwide waned. By 2000, Canadian production was

320,000 tons or 15% of world production, down from 43% in 1970. Canada produced about 61 million tons of asbestos between 1900 and 2000, all of it chrysotile (table 4).

Canada, for the most part, has been a major exporter of asbestos fiber over time. Roughly 77% of Canadian production has been exported since 1900 with exports exceeding 80% since 1960. The United States was the largest market for exported Canadian fiber. In 1930, U.S. asbestos imports from Canada were 181,000 tons or about 83% of Canadian production. This declined during the Great Depression in the United States in the early 1930s but picked up again during World War II. The United States imported about 65% of Canadian production in 1940. The ratio of U.S. imports from Canada to Canadian production was 78% in 1950, 37% in 1970 (as the asbestos health issue was developing), 6% in 1990, and 5% in 2000 (U.S. Geological Survey and U.S. Bureau of Mines Minerals Yearbook chapters on asbestos, 1900 to 2000).

Canadian asbestos producers had developed a broad range of customers before the decline of the U.S. market so those countries soon moved ahead of the United States as the major Canadian customers. As U.S. markets changed, the proportions of asbestos grades exported to the United States also changed. In 1973, the United States share of all Canadian exports was 34% (11 of 32 tons) of crude fiber, 24% (203,000 of 837,000 tons) of milled fiber (groups 3, 4, and 5) and 59% (498,000 of 846,000 tons) of short fiber (groups 6 to 9). Groups are asbestos product designations with group 3 containing a higher proportion of longer fibers than group 4, group 4 containing a higher proportion of longer fibers than group 5, and so forth. The United States was followed by Japan for crude fiber, West Germany, Britain, France, and Japan for the milled fiber, and Japan and Britain for short fiber. In all, Canada exported to more than 70 countries in 1973. By 1990, the United States had dropped to third (8% of 938 tons), behind Japan and Taiwan for the crude fiber, fifth (1% of 268,000 tons) behind Spain, the United Kingdom, India, and Sri Lanka for the milled fiber, and second (15% of 203,000 tons) behind Japan for short fiber. In 1999, the United States was grouped with other countries for all but the crude fiber because of the low import tonnage (Vagt, 1973, p. 43; Hoskin, 1990, p. 10.4-10.5; Perron, 1999, p. 17.9-17.11). Thus, Asian markets were relatively small in the 1970s but grew in dominance as markets shifted away from the United States and European countries in the 1980s. While a detailed account of all exports from Canada is beyond the scope of this paper, the Canadian Minerals Yearbook chapters on asbestos, published by Natural Resources Canada, contain such information if required.

4.3 Other market economy countries

Brazil

Brazil is a relative newcomer in the asbestos industry. While small amounts of asbestos were mined as early as 1932, it wasn't until 1967 that Brazil began significant production of chrysotile (Harben, 1984, p. 63). Even then, production was only 16,000 tons in 1970. In 1971, the industry received a boost because of the Brazilian Goals and Bases Program. About \$9.2 million was invested by the government to increase production (Clifton, R.A., 1973, p. 188). Within 10 years, production was almost 170,000 tons. Production peaked in 1991 at 237,000 tons. Following a decline to about 170,000 tons in 1995, production seems to have stabilized. Markets in Brazil were primarily those dealing with the manufacturing of asbestos-cement products (85% of sales for the dominant Brazilian producer) and friction products, including brakes and clutches (Kendall, 1996, p. 49; O'Driscoll, 1989, p. 34).

Export of asbestos began from Brazil in about 1980. In 1986, the major destinations for the largest Brazilian asbestos producer were Argentina, India, and Mexico with smaller shipments being made to China, Japan, Portugal, and Spain (Roskill Information Services, 1986, p. 14). By 1987, exports accounted for 25-30% of sales (O'Driscoll, 1989, p. 34). Exports were 73,000 tons in 1995 compared with 127,450 tons for domestic markets (Kendall, 1996, p. 49). Major destinations for exported fiber include Africa, Asia, the Far East, island nations of the Gulf of Mexico, and Latin America in the late-1980s (O'Driscoll, 1989, p. 34).

Cyprus

Cyprus was a small producer of chrysotile. Although mention of asbestos products appears in early Greek history, systematic mining of small amounts of asbestos did not occur until around 1907 (Anonymous, 1928, p. 39; Howling, 1937, p. 48). Significant commercial production did not begin until about 1950. Prior to that time, production was less than 15,000 tons, with that being attained only in the late 1940s. Production was affected drastically by World War II because Cyprus had an export-oriented asbestos industry. The industry recovered after the war. Within 25 years, production peaked at about 38,000 tons in 1976 (Maliotis and Ilich, 1986, p. 4). From there, a rapid decline occurred and production ceased around 1988. Exports were the key to the industry's survival. In 1962, about 69% of production was exported (May, 1964, p. 256, 259). By 1980, exports had reached 95% of production (Shekarchi, 1982, p. 280). As with Greece and Italy, markets were in Europe (Belgium-Luxembourg, Czechoslovakia, Denmark, France, West Germany, Greece, Ireland, United Kingdom), Africa (Egypt,), and Asia (India, Indonesia, Japan, Syria, Taiwan, and Thailand) (Roskill Information Services, 1990, p. A4). The bulk of these exports were used by the asbestos-cement industry (Virta, 1987, p. 148).

Greece

The earliest report of asbestos production in Greece was by Strabo in the 1st century and later by Solinus and Plutarch. They

indicated that the fiber was carded and woven into handkerchiefs (Evans, 1906, p. 143-144). Despite this early start, large-scale production of asbestos (mainly chrysotile) in Greece did not begin until the 20th century and even then, production was sporadic. Significant production did not begin until the early 1980s as production declined in other parts of the world. In 1981, a new mill and mine near Zidani were opened. Production progressed slowly as technical difficulties were encountered and the world asbestos markets were soft (Sassos, 1983, p. 66). Production increased to 66,000 tons in 1990, from 17,000 tons in 1982. In 1991, the mining operation had one of several financial problems, resulting in a drastic downturn in production. In 1992, the company began operating again under new management (Skillen, 1993, p. 37). Production in Greece increased to 80,000 tons in 1996, declining to 50,000 tons in 1998. Mining ceased in 1998 although fiber recovery from stockpiles and sales from stocks may have continued through 2001.

When the Zidani mine opened, the largest planned market was in asbestos-cement products. About 10% of the mine's output was to be used in other products such as floor tiles, asbestos paper products, putties, and paints (Industrial Minerals, 1978, p. 49). In 1980, 20% to 25% of production was used domestically (Clifton, 1981, p. 98). By 1993, 95% of the fiber was exported to Europe, the Far East, Middle East, and Brazil, predominantly for asbestos-cement and roofing applications (Skillen, 1993, p. 37). Around 1978, Greece was importing about 30,000 tons per year of asbestos for its own asbestos-cement industry (Industrial Minerals, 1978, p. 49).

Italy

Italy was the 2nd largest producer of asbestos in Europe, behind the FSU, for most of the 20th century. Italy was surpassed by Greece in 1989 only with the shut down of the Italian asbestos industry. Systematic production of Italian deposits began in the middle of the 19th century although manufacturing had been reported earlier (Alleman and Mossman, 1997, p. 71; Howling, 1937, p. 59). Even at that, production remained below 10,000 tons until 1941. Prior to the discovery of the Canadian deposits in the late 1800s, Italy supplied much of the world's asbestos needs (Bowles, 1934, p. 19; Howling, 1937, p. 59). Most of that early production was tremolite. After World War I, the Balangero mine near San Vittore opened and chrysotile comparable to Canadian fiber was produced in larger amounts (Howling, 1937, p. 62). After a brief decline during World War II, production increased steadily. Around 1968, the only operating mine in Italy upgraded its facilities to increase production (Icke, 1969, p. 187). Asbestos production peaked at 165,000 tons in 1976 and ceased in 1992. The Italian industry collapsed after the passage of government legislation banning the use of asbestos (Loughbrough, 1992, p. 43). Markets for Italian fiber included adhesives, asbestos-cement products, bitumen, electrical insulation, friction products, jointings, paper, and plastics (Mining Magazine, 1987, p. 25). In 1985, it was estimated that about 70% of domestic sales were for asbestos-cement applications (Craynon, 1988, p. 482).

Italy, having an active asbestos manufacturing industry, exported less than half of its asbestos production. Exports of 63,818 tons accounted for about 40% of production in 1981. The remainder was used domestically in asbestos-cement products (Roskill Information Services, 1983, p. 45). In 1984, exports were estimated to be 57,700 tons. Some of the countries importing Italian fiber were France, Germany, Poland, and Spain in Europe, Turkey in the Middle East, and India, Japan, Taiwan, and Thailand in Asia (Craynon, 1988, p. 470, 477). European countries and Japan were the largest customers, accounting for more than 50% of exports at times. Out of 57,659 tons exported in 1984, West Germany received 15,804 tons; France, 5,700 tons; and Japan, 5,699 tons. Italy imported crude fiber to meet demands, requiring 41,400 tons in 1984 (Sondermayer, 1987, p. 486).

South Africa

South Africa was probably the second most important market economy producer. Not only was South Africa the second largest market economy producing country from about 1950 to the 1980s, South Africa was unique in being a major source of several varieties of asbestos, mainly chrysotile, amosite, crocidolite, but also including smaller amounts of tremolite and anthophyllite. Asbestos production in South Africa began in the late 1800s but had progressed to only a few hundred tons by the start of the 20th century. Production increased slowly from 1900 to about 25,000 tons in the 1940s with only a mild downturn in the 1930s. After World War II, production grew rapidly, undoubtedly aided by major rebuilding efforts worldwide and growing economies starting in the 1950s. The number of mills in the Transvaal area increased from 6 to 27 in 1948-49, allowing for increased fiber production (South African Mining Journal, 1949, p. 527). Mining increased from 41,000 tons in 1948 to its peak of 380,000 tons in 1977 with only minor setbacks. Around 1956, the amosite and crocidolite producers resolved problems with mine pumping and ventilation although these problems didn't appear to affect production significantly (Kennedy and Mattila, 1958, p. 218-219). Chrysotile production capacity received a boost with the completion of a new mill near Barberton in 1969 (Readling, 1971, p. 190). With the asbestos health issue in the early 1970s, sales began to decline and, by 1977, producers were reporting higher than expected stocks, indicating that production was outpacing demand (Clifton, 1980, p. 154). Production in South Africa steadily declined to 18,800 tons in 2000. Chrysotile accounted for the largest share of production prior to 1938 and after 1982. Chrysotile production peaked in 1989 at about 115,000 tons.

South Africa was unique in that it was the major world supplier for amosite and crocidolite. Chrysotile, whose production began in 1905, was produced in lesser amounts in the country's early mining history (Anonymous, 1928, p. 30). Amosite was first mined in the Barberton District in 1907 and in the Pietersburg District in 1914 (Anonymous, 1928, p. 30; Kupferburger, 1930, p. 571). Crocidolite production was reported as early as the 1893 (Anonymous, 1928, p. 29; Diller, 1921, p. 555; Munzhelele, N.N., 1999, p. 194). Following an expansion program begun in 1948, amosite production increased through 1973 when it peaked at 106,000 tons;

crocidolite production peaked in 1977 at 201,000 tons. Amosite accounted for the largest share of production between 1938 and 1955. crocidolite dominated from 1956 to 1982. Demand for amosite and crocidolite began to decline in the early 1970s and late 1970s, respectively, in response to changes in the asbestos markets. Amosite mining ceased around 1992 although stocks still were sold after that time. Crocidolite mining ended in 1997 (Industrial Minerals, 1993; Mining Journal, 1992, p. 354; Munzhelele, 1999, p. 194; Republic of South Africa Department of Minerals and Energy, 1997, p. 20-22). Only small amounts of anthophyllite and tremolite were produced, generally on the order of only a few thousand tons annually, combined.

Like Canada, South Africa has been a net exporter of asbestos. More than 75% of South African production after 1960 was exported annually (Gössling, 1977, p. 75; Munzhelele, 1999, p. 197). For most years, exports were between 85% and 95% of production (although some of this amount was probably shipped from stocks during some years). Exports went to the Far Eastern countries, Middle Eastern countries, and European markets. Between 1935 and 1955, the United Kingdom and United States were the largest importers of fiber from South Africa. These two countries accounted for 27 % and 23% of exports, respectively, in 1954. These countries were followed by other European countries, Australia, Japan, India and Pakistan, and Latin American countries in 1954 (Bowles, 1959, p. 44). Total exports from South Africa in 1935 were 21,500 tons and 116,000 tons in 1954. By 1970, major importers of South African asbestos were Japan (33%), Italy (11.7%), the United Kingdom (9.5%), West Germany (9.3%), and France (6%). Only three years later, these export markets had changed to Japan (33.7%), Spain (15.2%), Italy (9.4%), the United Kingdom (7.8%), West Germany (5.8%), France (5.6%), and the United States (5.6%) (Gössling, 1977, p. 74). These same countries continued to be major markets as late as 1985. Other historical destinations included Austria, Belgium, Denmark, Taiwan, and Yugoslavia. South African exports peaked around 1975 at 339,000 tons, compared to a peak of 1.69 million tons in 1973 for Canadian exports. As with producers elsewhere, exports were impacted by the asbestos health issue (van der Merwe, 1989, p. 141). Partial or total bans on asbestos use in several European countries in recent years eliminated some former markets for the South African producers. Smaller losses in markets occurred with the downturn of the U.S. market after 1970.

Swaziland

Swaziland was a relatively small producer of chrysotile. Except for some sporadic mining, commercial production didn't really begin until 1939 with reported production to be about 7,000 tons. That was the year that the Havelock mine began operating (Bowles and Warner, 1940, p. 1372). Within three years, production had broken the 20,000-tons-per-year mark. Installation of an aerial ropeway through to the rail lines in 1941 eased a major transportation problem (Bowles and Petron, 1943, p. 1437). Over the next 35 years, demand rose slowly, intermixed with brief periods of downturns. For a brief period in the early 1970s, production suffered because of problems with rock stability in one of the underground mines (Clifton, 1975, p. 178). Production peaked in 1976 at 42,000 tons. After that, sales declined steadily. Production in 2000 was about 11,000 tons.

Like the other asbestos producing countries in Africa, Swaziland depended on exports to sustain its industries. The bulk of the production is shipped to other African nations, Europe, and the Far East. Most of the asbestos is used to produce asbestos-cement products. Shorter fibers were used for friction applications (Roskill Information Services, 1990, p. 48).

Zimbabwe (former Southern Rhodesia)

Zimbabwe is renowned for its production of low-iron, long fiber chrysotile. Mining began around 1908 (Anonymous, 1928, p. 35; Natural Resources Board of Southern Rhodesia, 1963, p. 16). By 1930, Zimbabwe, with 34,000 tons of production, was the third largest producer after Canada and the FSU. The opening of the Shabanie Railway in 1927 helped spur production by eliminating a major transportation issue (Bowles and Stoddard, 1930, p. 306). Competition from Russia affected Zimbabwean producers in the early 1930s although this was resolved by European customers apportioning orders between the two sources (Bowles and Stoddard, 1933, p. 750). Production again picked up by the mid-1930s and continued to increase as markets grew. Much of the increase was attributed to increased sales of short fiber chrysotile used by the asbestos-cement industry, albeit at the expense of the unit price (Bowles and Cornthwaite, 1937, p. 1368). Despite growing sales, Zimbabwe lost its third place standing to South Africa by 1950 but regained it again in 1985 when markets for South Africa's amphibole asbestos declined. Between those times, Zimbabwe declared its independence from the United Kingdom in 1965 and had United Nations economic sanctions imposed in 1966. Despite the sanctions from 1966 to 1979 and strikes in 1972, the companies continued to upgrade their production facilities and production and sales increased (British Sulfur Corp., 1972, p. 3; Clarke, 1982, p. 23; Clifton, 1974, p. 178; Clifton, 1982, p. 110). Production peaked at 281,000 tons in 1976. However, markets reversals resulted in a decline in sales and build-up of large stocks between 1978 to 1980 (Roskill Information Services, 1983, p. 68). Production declined to 115,000 tons in 1999 but rebounded to 145,000 tons in 2000. Markets for Zimbabwe remained strong through at least 2001.

Like South Africa, Zimbabwe depended on export markets to sustain its industry. About 97% of its production was exported to 50 countries by the early 1980s (Clarke, 1982, p. 23). The United Kingdom was the leading importer from 1935 to 1956 except during World War II, when the United States became the leading importer of Zimbabwean fiber. Other important markets were other European countries, Australia, India, and Latin America (Bowles, 1959, p. 43). In 1980, southeast Asia was a major market for Zimbabwean fiber because of its use in textiles (Industrial Minerals, 1980, p. 8). In 1982, it was estimated that Zimbabwe supplied about 50% of the world's asbestos fiber for textiles (Clarke, 1982, p. 23). Another market for the fiber was in asbestos-cement

products (Roskill Information Services, 1983, p. 68).

4.4 Current or former centrally-planned economy countries

China

Production of asbestos (mainly chrysotile) in China is difficult to track over time. As with many of the industrial minerals mining industries in China, accurate production and trade data on asbestos are difficult to obtain and frequently not available. The use of asbestos in China began more than 2,000 years ago, when asbestos was used to make fire insulation, asbestos paper, and fire pots (by mixing lime with asbestos). The most famous and earliest source for asbestos mined in China was Szechuan Province (Wang, 1981, p. 256). Production by individual companies operating in China between 1918 and 1928 was reported to be less than 100 tons combined (Anonymous, 1928, p. 44). Around 1934, production was estimated to be less than a few hundred tons (Bowles, 1934, p. 22). China became a moderate-sized producer of asbestos around 1960 when production was estimated to be 81,600 tons. By 1965, 10 new asbestos projects were believed to have been completed in Szechuan Province, after which asbestos production increased fairly rapidly (Wang, 1967, p. 1115-1116). Production was reported to be 209,000 tons in 1973. More than 12 up-to-date facilities mining and processing asbestos were on-line in Szechuan Province by 1975. By that time, Hopeh (Hebei) Province became the second largest producing region in China (Wang, 1978, p. 297-298). Production declined in the mid-1970s and early-to-mid 1980s. It was about 221,000 tons in 1990. Production increased to a peak of about 370,000 tons in 2000. With declining world markets, increased use of asbestos within China probably accounts for a large part of its increased production. Market data in China are not routinely published, but in 1985, it was reported that asbestos-cement products account for 51% of the asbestos usage in China (Chin, 1988, p. 216). Asbestos-cement markets still dominated in 1996, followed by friction products, rubber, textiles, and insulation products (Lu, 1998, p. 19).

China for the most part consumed most of its production internally and cannot be considered a world supplier of asbestos. Exports were mostly to southeast Asian markets. In 1962, exports were estimated to be 4,383 tons of the 90,700 tons of production, mainly to Japan and Poland. Asbestos exports were reported only to be 2,180 tons in 1974 (Japan receiving 1,394 tons in 1974 and Poland receiving 1,200 tons in 1975) and 10,430 tons in 1979. Exports in 1979 were shipped mainly to Hong Kong, Indonesia, and Thailand. Despite increased production, exports fell to 553 tons in 1986. Hong Kong, Singapore, and Thailand were the major destinations (Wang, 1967, p. 1112, 1115-1116; Wang, 1978, p. 289, 298; Chin, 1983, p. 233). Exports were reported as 9,392 in 1996, with Vietnam being the largest importer of Chinese asbestos (7,763 tons) (Lu, 1998, p. 19). Imports generally were not reported or not available over much of the history of the asbestos industry in China. Imports were reported to be 179 tons in 1973 and 839 tons in 1985 (Wang, 1978, p. 291; Chin, 1988, p. 207). By the 1990s, imports had increased, rising from 2,249 in 1991 to 77,958 tons in 1996. Of significance was the increased import of long-fiber asbestos. The major source for imported asbestos in 1996 was Russia (77,091 tons) (Lu, 1998, p. 19.).

FSU

Sinclair (1959, p. 3) reported that deposits in the Ural Mountains were first opened around 1720 with systematic mining of chrysotile on a commercial scale beginning in the early 1800s (Anonymous, 1928, p. 27; Howling, 1937, p. 62). Production in the FSU was initially concentrated in Bajenovna in the Ural district, providing about 85% of the supply by the 1920s (Bowles and Stoddard, 1931, p. 110; RuKeyser, 1933a, p. 335). By 1927, the FSU provided 11% to 15% of the world's supply of asbestos. Production, however, essentially stopped with federalization of the mines in 1918, World War I, the Russian revolution, and establishment of the Soviet State following the War (Bowles and Stoddard, 1930, p. 309, Howling, 1937, p. 62). Completion of a rail line that connected to the Trans-Siberian Railway in 1927 greatly improved access to the Uralasbest chrysotile deposit and made possible intensive development of the mines (RuKeyser, 1933b, p. 375). This rail line was replaced by a new line in 1931. The new line improved efficiency because it conformed to standard FSU gauge rail lines, eliminating the need to transfer equipment and product at the rail head (RuKeyser, 1933b, p. 375).

By the late 1930s, the FSU began to develop a large asbestos products industry, making the FSU both a major asbestos producer and consumer, and thereby reducing its dependence on foreign markets (Bowles and Stoddard, 1933, p. 751-752). Bowles (1934, p. 18) notes that exports declined from 51% in 1922-23 to 21% in 1934, reflecting the rapidly expanding domestic manufacturing industry. By the late 1930s, the FSU began taking steps to return to the status of a significant world producer. Around 1937, a 5-year plan (one of many) was developed that would increase capacity in the FSU to 220,000 tons per year (Bowles and Barsigian, 1943, p. 1432). Production increased gradually through 1982, except perhaps for World War II, for which data were not available. Contributing to the increase was the commissioning of the Dzhetygara chrysotile deposit in Kustanay Oblast in Kazakhstan in 1965. This was a year after the Tuvaasbestos complex in the Tuva Autonomous Republic was developed (Roskill Information Services, 1990, p. 57).

By 1975, the FSU had surpassed Canada as the world's leading producer of asbestos. Production in the Urals accounted for about 73% of the FSU output of asbestos, followed by Kazakhstan with 24%, and the Tuva Republic with 3% (Sutulov, 1973, p. 176). The Kiyembay asbestos combine in the Orenburg Oblast began operating around 1979-80. Upgrades were completed at Uralasbest

complex to improve mine efficiency. In addition, the Baikal-Amor Mainline Railway was developed to improve access to the Kiyembay complex (Industrial Minerals, 1985, p. 67). With these changes, the Uralbest complex's share of FSU production declined to about 62%. Uralbest, however, continued to provide all of the asbestos exported from the FSU (Clifton, 1982, p. 110). Production continued to increase until 1982, when production in the FSU peaked at about 2.7 million tons. By then, the health issue had begun to affect some of the export markets for FSU fiber. Further complicating the matter was the breakup of the Soviet Republic in 1991. Many industries, not just the asbestos industry, were affected by the ensuing financial difficulties immediately after the break up. Today, markets in the FSU are much less than in the peak production era although production was reported to have rebounded in 2001. The FSU continues to be the leading world producer of chrysotile with more than 900,000 tons of production annually.

In the 1960s, more than 80% of asbestos consumed in the FSU was used in roof tiles, wall panels, pipes, molded articles, and other building materials. Lower grades were used in manufacturing heat insulations and heat-resistant plastics. Treated mill wastes were used to make reinforced asphalt and roofing paper, filler in portland cement for concrete pipe, plaster, and protective coatings for metallic structures. Untreated asbestos mill wastes were used as railroad ballast and cold asphalt (Tverskoi, 1968, p. 31). In the late 1960s, major markets were roof tiles, wall panels, pipes, heat insulations, asphalt, roofing paper, asbestos-cement products, plasters, etc. (Tverskoi, 1968, p. 31). Asbestos-cement products are likely to be the dominant market in recent years.

Unlike China, the FSU eventually became a major factor in the world asbestos economy. In its early history, a significant percentage of production was exported. However, Bowles and Stoddard (1933, p. 751-752) observed that the asbestos manufacturing industry in the FSU was expanding rapidly in the early 1930s and consuming a larger share of domestic production. By 1961, exports from the FSU were 158,600 tons. The bulk of the exports went to Eastern and Western European markets, including West Germany (27,500 tons), France (25,500 tons), East Germany (14,000 tons), Czechoslovakia (12,700 tons), Bulgaria (12,000 tons), Poland (11,300 tons), Hungary (10,100 tons), and Japan (8,800 tons), in decreasing order by tonnage (Sokoloff, 1964, p. 760). By 1964, exports had increased to 180,000 tons. Exports expanded rapidly after that, reaching 346,500 tons in 1969 and 385,000 tons in 1970. In 1968, Tverskoi (1968, p. 31) reported that the FSU exported asbestos fiber to more than 30 countries. By 1970, Japan had moved into second position with regard to export destination with 43,900 tons, preceded by France with 53,000 tons. West Germany followed with 43,100 tons, Poland (31,500 tons), Bulgaria (21,200 tons), Czechoslovakia (21,100 tons), Yugoslavia (20,600 tons), and Romania (16,300 tons) (Strishkov, 1973, p. 832). Exports increased to 527,971 tons in 1974. There appears to be a major unexplained decline in exports in the late 1970s to early 1980s. Exports were only 315,780 tons in 1980. Some of this may be the result of health concerns in western countries regarding exposure to asbestos. Also, exports to the western European and Asian markets had declined somewhat but it does not explain the entire phenomenon. Exports recovered by 1985 (reported as 600,000 tons). In the early 1980s, centrally-planned economy countries accounted for about 50% of exports from the FSU (Roskill Information Services, 1983, p. 64). By 1988, declining asbestos consumption worldwide and possibly internal issues resulted in a decline in exports to 400,000 tons. Exports in 2000 were estimated to be about 506,000 tons (British Geological Survey, 2002, p. 26).

4.5 Other producing countries

While the bulk of the asbestos was produced by the above countries, many other countries produced small amounts of asbestos that filled essential markets. For example, Finland was the world's primary source for anthophyllite asbestos from about 1919 to 1975. Production in Finland was relatively low over time, exceeding 15,000 for only a few years in the late 1960s. After that production declined and finally stopped in 1975. Crocidolite was produced in Australia and Bolivia. Australia began producing asbestos around 1916. Production increased slowly to 16,200 tons in 1962. It declined rapidly to 666 tons in 1967 after Australian Blue Asbestos Pty. closed its Wittenoom mine in 1966 (Morrell, 1969, p. 99). Production increased in the early 1970s to meet world demand, peaking at 92,000 tons in 1980. No production, however, was reported after 1983. Bolivia produced only small amounts of crocidolite over the years, on the order of only a few hundred tons. India was a source for anthophyllite and tremolite asbestos as well as chrysotile. Production began around 1917 and eventually reached 44,100 tons in 1993. Production declined to 14,500 tons in 2000. Japan and South Korea also were important sources of mainly chrysotile for Far Eastern asbestos markets during various periods of the 20th century. Production in Japan began by 1920, peaked at 27,000 tons in 1967, and declined to 18,000 tons in 2000. Production in Korea began in the early 1930s. Its production peaked at 15,900 tons in 1982. Production was last reported in 1992. A host of other countries also provided even smaller amounts (less than 5,000 tons) of asbestos for domestic or export markets.

5. WORLD CONSUMPTION

As with all commodities, world consumption patterns for asbestos have evolved over time. Changes have occurred because of technological progress (industrialization and the development of an asbestos manufacturing industry), availability of asbestos either domestically or through imports, political changes (civil unrest, independence movements, or sanctions), regulatory bans on its use, world conflicts, liability issues, and foremost in recent years, health issues. By tracking apparent consumption (production plus imports minus exports), a general idea of the changes that have occurred in the worldwide use of asbestos over time is possible.

Bowles (1955, p. 59; 1959, p. 32) noted that it is much more difficult to determine apparent consumption than production. What applied in the 1950s is still true today. Manufacturing from consumer stocks, sales from producer stocks, and consumer and producer stocks that have been held over from year to year complicate the estimation of apparent consumption as do the limitations of the data

as discussed in the “Data Sources” section. Overcapacity, particularly after the asbestos health issue was raised, resulted in a significant share of production going into stocks for some countries in some years. The changes in stocks result in some error in the apparent consumption since the calculation does not typically account for additions and subtractions from stocks. Overcapacity and a build-up of stocks resulted in an overestimation of consumption in Canada, the RSA, Swaziland, and Zimbabwe at times. Overcapacity and questionable export data for the FSU began to appear after 1997, skewing the calculated consumption in Europe and the world total consumption. Consequently, the following discussion should be viewed as an approximate measure of apparent consumption and utilized to determine trends in the apparent consumption of asbestos rather than its absolute consumption. A detailed breakout of calculated apparent consumption, by country, is given in Appendix A for 1920 to 1970 in 10-year intervals, 1970 to 1995 in 5-year intervals, and 1996 to 2000 annually.

Although the modern asbestos industry first began in Asia and Europe, it was the United States that fully embraced its potential, becoming the largest consuming country in the world for much of the 20th century (table 5). The reason is that the United States offered the greatest opportunities for the relatively new asbestos industry. The country's population centers were expanding rapidly with the surge in immigration in the early 1900s, there was available capital for investment in the asbestos industry, and there was a large demand for construction of housing, public buildings, and roads. To meet these demands, the construction industry not only expanded but also evolved through technological developments, creating an opportunity for the relatively new asbestos industry to establish itself. Thus, the use of asbestos exploded in the United States unlike anywhere else in the world. The United States became a world leader in usage within a couple of decades of having begun its asbestos industry and held that position through the 1960s.

From 1920 through the 1960s, the United States accounted for 30% to 83% of world apparent consumption for the 10-year intervals examined. It wasn't until the 1960s that the United States was replaced by the FSU as the leading consuming country (Appendix A). The next nearest competitor was Japan, which had attained a consumption level of 319,000 tons in 1970. A detailed discussion of U.S. consumption of asbestos has already been presented in the “World supply and trade” section of this paper.

Other countries in North America also consumed small relative amounts of asbestos. These included Canada, Costa Rica, Cuba, the Dominican Republic, El Salvador, Guatemala, Honduras, Jamaica, Mexico, Nicaragua, and Panama. Most of these countries were small consumers, using only a few thousand tons annually. Canada was primarily an exporter but its calculated apparent consumption was 106,000 tons of asbestos in 1980. This, however, was probably a case of oversupply as world markets began to decline. A large part of the 106,000 tons probably went into stocks rather than commerce. Consumption of around 45,000 tons annually probably would have been the norm from 1940 to 1970 and less after the 1980s. Consumption in Mexico gradually built up to 79,000 tons in 1980 from an annual consumption of only 390 tons in 1930. After 1980, consumption declined, eventually reaching 26,900 tons in 2000. In 2000, El Salvador and Panama were the only other North American countries indicating consumption.

After the United States, Europe was the next region to develop an asbestos manufacturing industry. The United Kingdom, receiving its asbestos from other parts of its world empire, became the major European consumer through the first half of the 20th century (table 5). The United Kingdom was soon followed by many other European countries. By 1930, Belgium-Luxembourg, Germany and the United Kingdom were major suppliers of asbestos products throughout Europe and Asia. The FSU was the next largest producer and consumer of asbestos with its need to supply itself and other centrally-planned economy countries. Demand in the FSU exceeded that of the United Kingdom by 1950 and by 1970 that of the United States, thanks largely to large construction demands.

There were 16 European countries consuming 40,900 tons of asbestos in 1920. By 1930, estimated consumption had increased to 127,700 tons. Austria, Belgium-Luxembourg, Cyprus, Germany, Italy, the FSU, and Spain experienced the largest growth in consumption before 1950 (table 6 and Appendix A). Between 1950 and 1960 the asbestos industry in Europe experienced its greatest expansion up to this time, increasing to 1.17 million tons from 507,000 tons in 1950. During the decade of the 1950s, consumption in Austria, Belgium-Luxembourg, Czechoslovakia, Denmark, France, the FSU, West Germany, Italy, the Netherlands, Poland, Spain, Sweden, Switzerland, the United Kingdom, and Yugoslavia increased considerably. The largest gains were in the FSU (317,000 tons), the United Kingdom (55,400 tons), and West Germany (52,400 tons). Much of the growth in consumption in the late 1940s and a large portion of the 1950s can be attributed to the massive reconstruction efforts in Europe following World War II. Estimated consumption in Europe increased to 1.8 million tons in 1970 and 2.8 million tons in 1980. The largest growth was in the FSU, increasing by slightly more than 1 million tons between 1960 and 1980.

The asbestos health issue, which affected U.S. markets by the mid-1970s, also began to affect asbestos in Europe. After 1980, demand in all large consuming European countries, except the FSU, began to decline. This pattern continued through 1990, with only the FSU maintaining its consumption levels. In 1990, consumption in Europe was 2.58 million tons.

The 1990s was a decade of change for the European manufacturing industry. During that time, the FSU was restructured and many European countries and eventually the European Union voted to ban the use of asbestos. From a tonnage standpoint, the restructuring of the FSU had the biggest impact. By 1995, estimated consumption in Europe had declined to 928,056 tons and by 2000, it reached an estimated 341,000 tons. Several important consumers of asbestos in Europe are Azerbaijan, Belarus, Croatia, Hungary, Kazakhstan, Kyrgyzstan, Portugal, Romania, Russia, and Spain (Appendix A). There still many smaller yet important consumers, including Greece, Ireland, and several of the former Soviet bloc countries.

There is some uncertainty in the consumption data from 1998 to 2000 because of an imbalance in the reported supply and demand relationship. More exports than imports were reported during this period worldwide. Most of the imbalance resulted from an apparent increase in reported exports from former FSU countries. Exports from other producing countries are in line with current world

consumption trends. It is likely that the FSU export data are overestimated, with some asbestos of the reported exports being stockpiled, some asbestos being consumed within the FSU, and some actually being asbestos waste used as road gravel rather than fiber. Apparent consumption for all countries, except possibly Kazakhstan and Russia, are believed to be reasonably accurate during this time period despite the supply and demand imbalance.

Growth in the Asian (including Middle Eastern countries in the following discussion) asbestos manufacturing markets lagged behind that of Europe and the United States. This can be partially attributed to less initial industrial development in most Asian countries in the early 20th century, slower population growth which resulted in lower demand for infrastructure development, cultural differences guiding infrastructure and technological development, Governmental policies regarding industrial development, and fiscal restraints affecting the start-up of new industries or importation of new products.

Very little asbestos was used in Asia in 1920; only 6,810 tons by 3 consuming nations (table 5). It wasn't until the 1950s that a serious manufacturing industry developed. Estimated consumption in 1960 was 222,000 tons in 16 countries, a dramatic increase from only 25,400 tons in 1950. China and Japan accounted for the bulk of this increase (table 6 and Appendix A). Asbestos consumption in Asia increased to 667,000 tons in 1970 from 222,000 tons in 1960. Again, China and Japan accounted for the largest increases in consumption. Smaller increases occurred in India, Iran, South Korea, Malaysia, Thailand, and Turkey. Japan was the most consistent large user of asbestos from 1920 to 1970. Estimated consumption in Asia increased to 1.06 million tons in 1980. By this time, more Asian countries were manufacturing asbestos products and considerable gains were made in China, India, Indonesia, Iran, Japan, South Korea, Malaysia, Saudi Arabia (a one-time occurrence), Taiwan, Thailand, and Turkey.

The 1980s brought about a shift in manufacturing in Asia. Estimated consumption declined in China, Japan, Malaysia, Saudi Arabia, and Taiwan but increased in India, Indonesia, Iran, South Korea, and Thailand. There was an increase through 1995 in Asian consumption to 1.26 million tons from 975,000 tons in 1990. China accounted for the bulk of the increase followed by, in decreasing order by tonnage, Thailand, Indonesia, South Korea, and Malaysia. By 2000, estimated consumption had declined to 871,000 tons, less than in 1990. Iran, Japan, and South Korea experienced the largest declines (table 5 and Appendix A).

In 2000, China accounted for 50% of the apparent asbestos consumption in Asia, which was used mainly to satisfy its own domestic needs. Thailand was the next largest consumer with 15% of the market, followed by Japan with 12%, India with 8%, Indonesia with 7%, and South Korea with 4%. Consumption in most Asian countries has continued to decline through 2000, the exceptions being China, India, Indonesia, and Thailand (Appendix A). Countries such as Iran, Oman, Pakistan, Singapore, Taiwan, Turkey, and the UAR still maintain a small presence in the asbestos-manufacturing sector.

Consumption in Africa has been rather low throughout most of the 20th century, peaking only in the 1990s. Slow population growth, limitations on land amenable for development, slower dissemination of technological developments, Governmental policies toward development, and fiscal restraints influenced the development of the asbestos industry in Africa. Even the asbestos-producing African nations, despite having manufacturing facilities, exported the bulk of their fiber production to foreign manufacturing markets. Only a few African countries used asbestos in the 1920s. Estimated consumption was about 3,530 tons in 1920 (table 5 and Appendix A). Egypt, Madagascar, and Zimbabwe and probably South Africa had small manufacturing industries. This situation did not really change significantly until the 1950s. In that decade, consumption had risen to 9,600 tons and 11 countries were involved in asbestos manufacturing. Algeria, the Belgian Congo, Egypt, Morocco, Swaziland, and Zimbabwe were the largest consumers. Estimated consumption increased to 90,300 tons in 1970 from 28,600 tons in 1960. Between this time, the number of countries involved with manufacturing asbestos products increased from 12 to 15. The largest increase in consumption was in Nigeria, having the largest population, where consumption increased by 34,400 tons, and Zambia, which increased to 15,600 tons in 1970 from no reported consumption in 1960 (table 6). Nigerian imports varied considerably over time, suggesting stockpiling during one year and use over several years. Nigerias asbestos manufacturing industries grew after the 1960s to accommodate its growing population needs. After the 1970s, consumption in most countries in Africa began to decline. The notable exception was Algeria, whose consumption was 21,300 tons in 1980 and 17,400 tons in 1990. Its consumption, however, had declined to 10,000 tons by 1995, 900 tons in 2000, and 4,100 tons in 2001. A few other African countries, particularly in recent years, have developed small manufacturing industries to meet demand for construction materials. Apparent consumption data for Africa in 2000 is difficult to ascertain as reliable data is not yet available for Egypt, Morocco, Nigeria, Tunisia, and Zambia.

The asbestos industry in South America did not begin to have significance in the world markets until the 1960s. Prior to that time, there was little asbestos production or consumption (table 5). What little production there was existed to fill niche markets rather than to meet growing world demands. Argentina, Bolivia, Brazil, Chile, Peru, Uruguay, and Venezuela were the major South American consumers of asbestos during the early part of the 20th century. Up until 1960, consumption in South America was about 38,100 tons.

Brazil had just begun production to supply its own markets, but South America was dependent on imports for about 65% of its fiber consumption. By 1970, Argentina, Brazil, Colombia, and Venezuela had the most active of the asbestos manufacturing industries in South America. Even at that, consumption was estimated only to be 99,200 tons. By the mid-1970s, though, Brazilian production expanded to meet the country's demands, and Brazil soon became the dominant South American producer and consumer of asbestos (table 5 and 6). In 1980, Brazil accounted for about 73% of the continent's asbestos usage of 267,000 tons. Brazil was followed by Colombia with 27,100 tons, Argentina with 21,400 tons, and Venezuela with 9,100 tons. Chile, Ecuador, Peru, and Uruguay used lesser amounts (Appendix A). With the onset of the asbestos issue, consumption in most South American countries declined. That of Brazil, however, still exceeded 182,000 tons in 2000.

Oceania consists of Australia and New Zealand. Both countries produced and consumed asbestos in the early part of the 20th

century. Consumption rose gradually through the mid-1970s when it peaked at 85,700 tons in 1975. Australia accounted for 73,200 tons of this total. With the asbestos health issue of the 1970s, production and consumption declined rapidly. By 1990, New Zealand had stopped using asbestos and in 2000, Australia's consumption was only 1,250 tons (table 5).

In general, economic, political, and social agendas; different philosophies on how to meet those agendas; and different asbestos resources available guided the development of the asbestos manufacturing industry in any given country in terms of the size of its industry and the types of products manufactured. If countries required an asbestos industry to meet their expansion needs, the industry developed. The growth was logical in that demand for asbestos products, most notably asbestos-cement products, was greatest in countries undergoing extensive infrastructure development.

Few historical data on asbestos markets are available. Even in the United States, an annual survey of consumption was not developed until 1972 with projections back in time to 1965 (table 3). Bowles (1937, p. 82-87) reported on the asbestos manufacturing industries in major producing countries. From his qualitative descriptions of the industries in the manufacturing countries, it can be inferred that asbestos-cement corrugated and flat sheet, pipe, and roofing tile were the major markets for asbestos around 1930. The low cost of asbestos-cement products, their durability and effectiveness, and the relatively unsophisticated technology required to produce asbestos-cement products were major factors leading to its widespread use, particularly for developing countries with limited mineral and monetary resources. In regions where there were alternative construction materials, the demand for asbestos-cement products was proportionally smaller, and a much wider variety of other asbestos products was developed. In 1980, asbestos-cement products accounted for approximately 66% of world consumption of asbestos. The United States and western European countries were less dependent on asbestos-cement products than other regions. Asbestos-cement accounted for 45% and 43% of the U.S. and western European market usage, respectively. Asbestos-cement products accounted for 80% of asbestos products manufactured in Africa; 76% in Asia, eastern European countries, and South America; and 60% in Oceania in 1980 (Roskill Information Services, 1983, p. 85-86). With the decline in the use of asbestos in the 1980s and 1990s, markets shifted even more to favor asbestos-cement products. In 2002, asbestos-cement products are thought to account for more than 98% of the world's consumption of asbestos (Virta, 2002, p. 18).

6. DISCUSSION

Asbestos has had a long and, until the past 35 or so years, illustrious role in modern society. Over the course of its history, asbestos has been used in thousands of products for a vast number of applications. These applications ranged from roofing shingles to water supply lines to fire blankets to plastics fillers to medical packings (Rosato, D.V., 1959). It was used commonly by both industry and the general public. A glance at almost any home repair book written before about 1955 will show that asbestos was treated as just another tool by the home handyman (Cobb, 1948, p. 129-130). That it was so widely accepted is a tribute not only to its versatility but also, ironically, to a lack of knowledge about the risks posed by exposure to high levels of airborne asbestos dust. The British first raised health concerns in the early part of the 20th century, but it was not until the late 1950s and early 1960s that a correlation between excess exposure to asbestos fibers and respiratory cancer diseases was established (Gross and Braun, 1984, p. 20-21; Selikoff and Lee, 1978, p. 22-23, 31-32; U.S. Department of Health and Human Services, 1992, p. 289-290). Thus, the asbestos health issue did not arise until long after asbestos had been used by society for a long period of time. Asbestos is not alone in this respect. The discovery of adverse health effects after a material has been used for decades or even centuries is not unusual. A few examples are arsenic, beryllium, lead, mercury, uranium, and some fertilizers and insecticides.

With these concerns over the health risk, many ask why and how the asbestos industry developed in the first place and why it continues to operate. One has to consider the knowledge of health risks throughout history and the state of technological development.

As mentioned in the previous paragraph, the connection between excessive exposure and lung cancer was not firmly established until the late 1950s and early 1960s. Thus, the industry was more than 100 years old before the lung cancer and mesothelioma issues would be fully recognized and addressed. Further complicating the matter was that health researchers had different opinions themselves over the health risks posed by excessive exposure to asbestos. Even more recently, some researchers have suggested that chrysotile is not as carcinogenic as amphibole asbestos varieties and that little risk has been posed by nonoccupational exposures to chrysotile (Hoskins, 2001, p. 251; Ross, 1984, p. 51).

From a technological standpoint, asbestos was and still is, in some cases, the best choice and sometimes the only choice for a product. Had the asbestos industry not been developed in the late 1800s, solutions to problems that were readily solved by using asbestos would have been more complex. The reason is that many substitute materials or substitute products on the market today that were not available or were not practical to use until late in the 20th century. For example, wollastonite is a substitute for asbestos in some applications. Wollastonite was not even considered as a substitute for asbestos until the 1960s and from a supply side, large-scale wollastonite mining did not begin until the 1950s. Cast iron water supply pipe was not the best choice for use in alkaline soils, as in the southwestern United States. Asbestos-cement pipe was the solution to that problem. Plastic pipe, another possible solution to the alkaline soil problem, was not developed until the later part of the 20th century. In the 1800s, wooden structures were still commonplace and a fire could be devastating for a city. Hence, a demand for asbestos textiles and asbestos board developed. One substitute for asbestos in textiles, the fire-resistant aramid fiber, was not commercialized until the 1970s. Early brake and clutch components had limited performance capabilities so asbestos brakes and clutch components were developed. These are just a few of the reasons as to why the industry established itself and thrived. Although a health risk was posed by excessive exposure to airborne asbestos, asbestos solved many health and safety issues (reducing fire risks and improving component performance) and energy

conservation issues (thermal insulations) as well as proving itself a valuable construction material that helped to further the development of society. Its use continues today in many parts of the world because of a need for inexpensive and durable (primarily asbestos-cement) products that require simple technology to make and do not require large capital investments.

Despite its continued use, the overall trend in asbestos consumption is downward. The largest declines have been in the United States, most European countries, Oceania, and even in many developing countries. There was a slight increase in asbestos consumption in Africa between 1990 and 1996 (excluding South Africa, Swaziland, and Zimbabwe, which already had small yet long established manufacturing industries). Countries such as Algeria, Egypt, Morocco, Tunisia, and Zambia increased their consumption starting in the late 1970s. Since the mid-1990s, however, consumption in those countries has declined. Only Nigeria and Senegal maintained their levels of consumption through 1999. Nigeria, having the largest population, probably was the largest consumer of asbestos in Africa through 1999, assuming that some of the apparent consumption in South Africa, Swaziland, and Zimbabwe was overestimated because of asbestos actually being placed into stocks. Firmer data for 2000 and 2001 will be required to determine if the overall decline in 1998 and 1999 in African consumption continued.

Asbestos consumption in Latin America declined in recent years although Mexico still remained a sizable consumer in 2000. El Salvador was the only Latin American country that appears to have increased consumption through 2000. The overall trend in South America also has been downward from the mid-1990s. Exceptions in Brazil, whose consumption increased slightly through 2000 and Ecuador and Venezuela, whose consumption declined through 1990 and then began to increase after 1995. Consumption in Colombia declined from 1996 to 1999 but increased in 2000. It is not known if this trend will continue. Consumption in Bolivia, Chile, Peru, and Uruguay was the reverse, with consumption increasing through the mid-1990s and then declining.

In Asia the overall trend has been downward for consumption. China, India, Japan, and Thailand were the largest Asian consumers of asbestos in 2000. There are a few lesser-consuming countries (Indonesia, Malaysia, Sri Lanka, and Thailand) whose consumption has rebounded in the past couple of years. Additionally, Iran, Oman, Pakistan, Philippines, Republic of Korea, and Taiwan are a few Asian countries that still appear to be maintaining low levels of asbestos manufacturing capability in recent years.

In Europe, Azerbaijan, Belarus, Kyrgyzstan, Portugal, Romania, Russia, and Spain were important consumers in 2000. Consumption in most western and central European countries declined sharply in the 1990s. A few FSU countries (Azerbaijan, Belarus, and to some extent, Kyrgyzstan and Russia) have increased their consumption but most have not. Apparent consumption in countries such as Bulgaria, Croatia, the Czech Republic, Hungary, Lithuania, Portugal, Romania, Spain, and Yugoslavia, yet they have maintained low consumption levels (less than 5,000 tons per year with the exception of Spain) for the past few years. With the European Union ban on asbestos becoming effective in the next couple of years, presumably the FSU countries will remain as the largest consumers of asbestos in Europe.

In summary, world consumption has declined. Those countries experiencing the largest declines or gains in consumption over time are given in table 6. Where low-level asbestos manufacturing industries remain, they appear mainly to be remnants of a past industrial capacity. In a few countries with small manufacturing industries, though, consumption has increased, possibly owing to the loss of foreign sources for some asbestos products. It is doubtful if the industries in these countries will expand much beyond their current capacity given the negative atmosphere regarding the use of asbestos worldwide and the greater availability of asbestos substitutes (many of whose potential long-term health risks, ironically, are unknown) and alternative materials.

7. CONCLUSIONS

Asbestos, despite being a carcinogen, was widely used by society. Without asbestos, the development of many products would have been delayed and ironically, without many of the asbestos-containing products, health and safety could have been jeopardized. That asbestos is more versatile than many of its contemporary competitors cannot be denied. Following World War II, there was a large effort to synthesize asbestos and to develop asbestos substitutes from a strategic, not a health, viewpoint. Neither the synthesis nor the substitutes were immediately successful. An additional 20 years would elapse before substitutes would make inroads into the asbestos market. To its credit, it has taken a plethora of materials to substitute for asbestos in manufacturing.

The adverse publicity on asbestos and lawsuits have taken their toll on asbestos markets, despite much stricter asbestos regulation. Worldwide consumption declined from an estimated 4.84 million tons in 1980 to about 1.48 million tons in 2000. Public pressure and liability issues have forced most companies to stop manufacturing asbestos-containing products and forced many companies into bankruptcy. While there are still a few countries that have increased or maintained their production in recent years, consumption has fallen off dramatically in most countries. The largest consumers in 2000 were Brazil, China, the FSU, India, Japan, and Thailand, which accounted for more than 90% of world estimated consumption (83% of apparent consumption). Consumption has increased in India, Indonesia, and Thailand during the past couple of years while that of Japan has declined. Several countries have maintained low levels of consumption and a few of these small consumers have increased consumption in recent years.

TABLE 1
EARLY DEVELOPMENTS OF THE ASBESTOS INDUSTRY

1857-1880	First packings and flat seals
1866	First bonded and molded asbestos product for heat insulation
1868-1969	First U.S. use of asbestos in roofing felt and cement
1866-1876	Start of systematic textile processing in Italy
1878	Asbestos paper first made in the United States
1882	Concept of asbestos-containing magnesia insulation developed
1890	Textile processing begins in Canada
1893	First spinning of crocidolite in Republic of South Africa
1896	First woven brake bands made in England
1899	Wet machine process of making asbestos-cement developed
1900	Hatschek machine for manufacturing asbestos-cement pipe designed
1903	Asbestos-cement pipe industry begins in the United States
1904	Flat asbestos-cement board manufactured in the United States
1906	Asbestos first used as brake lining
1918	Molded clutch facing developed
1931	Technique for spraying asbestos developed in England
1940s	Asbestos-cement pipe introduced into England
1944	Spraying of deckheads and bulkheads began in British naval ships

⁶Estimated. NA Not available. W Withheld to avoid revealing company proprietary data. -- Zero.

¹Production plus imports minus exports minus changes to Government and industry stocks.

²U.S. Census Bureau reported number. Crocidolite imports estimated to be less than 5 tons.

¹Data are rounded to no more than three significant digits; may not add to totals shown.

²Part of the change in consumption in major asbestos-producing countries such as Canada, FSU, and RSA includes asbestos that has been added to or removed from company stocks in addition to that used in manufacturing.

Source: Calculated from data in Appendix A.
