the area of the reservoir surface will be about 1,000 acres and the storage capacity 10,000 acre-feet.

Conduit.—The one unit installed is supplied by two riveted-steel pressure pipes, 10 feet in diameter and about 200 feet long, supported on masonry piers. These pipes, leaving the gatehouse of the dam, run nearly horizontal for a short distance, then bend downward and laterally through an angle of nearly 90° to the back wall of the power house, where they are tapered to a diameter of 8 feet for connection with the turbine casings. Water is admitted to the pipes through trash racks and sliding gates in the gatehouse at the north abutment of the dam, and immediately below the gatehouse there is a 30-foot standpipe in each line. The static head from the lip of the spillway (2,574 feet above sea level) to water surface in the tailrace (2,468 feet above sea level) is 106 feet. The upper lip of the draft tube is 2,466 feet, and the lower lip of the draft-tube outlet is 2,450.6 feet above sea level.

Power house.—The Copco power house (Pl. XVI, *A*) is on the north side of Klamath River immediately below Copco dam. It is built of reinforced concrete supported on heavy concrete foundations that extend down to bedrock. The corrugated galvanized-iron roof, with louver ventilator, is supported on steel trusses. The building is to be extended at the downstream end to a length of 134 feet, but in 1921 only the upstream half of the structure had been constructed. The total inside width of the power house is 57 feet 6 inches and is divided into a generator room 44 feet 6 inches and a series of bays 13 feet wide. The generator room is 26 feet high from floor to crane rail and 33 feet 1 inch from floor to the lower chord of the roof trusses. The generator room extends the entire length at the back, and the transformer and switchboard bays the entire length of the front of the building. There is a horizontal tunnel under the generator room and another under the transformer bays. The floor of the power house is 2,483.9 feet above sea level, and the generator shaft is 2,488 feet above sea level. Two 40-ton cranes command the generator floor.

Hydraulic equipment.—The single unit is operated by an Allis-Chalmers turbine of the double inflow type. As originally designed, both runners were to be under a single housing and were to be supplied by a 17-foot pressure pipe. This arrangement was changed during construction and the turbine is provided with a double-scroll case, each 120-inch runner being supplied by a 10-foot pipe. The rated capacity of the turbine is 18,600 horsepower, and it is designed to operate under the ultimate head of 125 feet.

Generator.—The single generator is a General Electric 12,500-kilovolt-ampere (16,750 horsepower) 2,300-volt 3,140-ampere 3-phase

60-cycle horizontal machine, direct-connected to the turbine shaft and operated at 200 revolutions per minute. The unit is controlled by an Allis-Chalmers governor.

Exciters.—Two General Electric 250-volt 200-kilowatt exciters, sufficient to provide exciting current not only for the present but for the ultimate installation, are now in place. Each exciter is direct-connected to an Allis-Chalmers Francis turbine, rated at 300 horsepower and designed to operate at 720 revolutions per minute under a 125-foot head. A flywheel is mounted on the shaft between the turbine and the exciter generator, and each exciter unit is controlled by an Allis-Chalmers governor.

Transformers.—The single unit now installed is connected through double busses to two banks of three General Electric 4,165-kilovolt-ampere single-phase water-cooled transformers, giving a total transformer capacity of 24,990-kilovolt-amperes, or sufficient for the development planned. One bank is delta connected, giving 34,000 volts, for delivery to the line running from the Fall Creek plant east to Klamath Falls. The other bank is Y connected, grounded, and joined by a short stub line to the 60,000-volt main transmission line running south from the Fall Creek plant.

CARRVILLE PLANT.

LOCATION.

The Carrville plant is near the junction of Coffee Creek with Trinity River. The intake is about 2½ miles above that junction, in the NW. ¼ sec. 7, T. 37 N., R. 7 W., the conduit traverses secs. 7 and 8 to the forebay at the head of the pressure pipe in sec. 17, and the pressure pipe runs southeasterly to the power house in the southeast corner of the NW. ¼ NW. ¼ sec. 17 of the same township.

The plant was constructed by Trinity Gold Mining & Reduction Co. It was purchased by California-Oregon Power Co. and connected June 1, 1916, to its transmission line serving the Trinity River mining district.

SOURCE OF WATER SUPPLY.

Coffee Creek, from which the Carrville plant obtains its water supply, drains an area in the northern part of Trinity County, in the northwestern part of the State (Pl. XVII). The average length and width of the basin are about equal, between 10 and 11 miles, and the total area above the intake of the power plant is 114 square miles. Elevations within the basin range from 2,500 feet up to 8,250 feet above sea level, most of the area exceeding 5,000 feet. The general course of the stream is eastward from its headwaters in the Salmon River Alps to its junction with Trinity River. Its principal tribu-

ELECTRIC SYSTEMS.

FOLSOM PLANT.

LOCATION.

The Folsom plant, the first hydroelectric station to begin operating in central California, was put into service July 13, 1895,[20] by Sacramento Electric Power & Light Co. The power house is on American River, in sec. 35, T. 10 N., R. 7 E., on the outskirts of the town of Folsom, a short distance from the Southern Pacific Railway station. The intake of the canal is in sec. 24, T. 10 N., R. 7 E.; the conduit traverses secs. 24, 25, 36, and 35 of the same township.

SOURCE OF WATER SUPPLY.

The Folsom plant is operated by water taken from American River a short distance below the junction of the South and North forks of that stream. The Middle Fork enters the North Fork 16 miles above the canal heading. The drainage basin above the intake includes 1,865 square miles, lying south of the main line of the Southern Pacific (which runs along the ridge between the North Fork of the American and the Bear River basins) and on all three forks of the river. The basin is chiefly in Placer and Eldorado counties, between Sacramento and Lake Tahoe, but a very small part of its northern edge extends into Nevada County and the extreme southeastern tip into Amador and Alpine counties. The distance from the eastern boundary of the basin at the main crest of the Sierra to the westernmost point, at the canal intake, is about 55 miles. The width of the basin due south from Emigrant Gap is about 40 miles. Elevations range from 210 feet at the intake to about 10,500 feet on the highest peaks, and the general elevation on the eastern boundary is about 8,500 feet.

From the headwaters to its junction with the Middle Fork the North Fork flows southwesterly, and the stream below the junction continues in the same direction. The Middle Fork flows almost due west from the Sierra divide, as does also the South Fork. The three forks dominate the topography of the area, dividing it into three deep canyons. West of Placerville, Georgetown, and Colfax, the lower mountains break away into a foothill belt which extends nearly as far as Folsom.

The rocks exposed along the crest of the Sierra Nevada within the basin are chiefly granites, but farther west are andesites and in certain places, chiefly along the ridges, lavas.

The central part of the basin is well forested, especially along the ridges at elevations between 3,500 and 5,000 feet. At higher elevations the soil is thin and the characteristic features of the country are

---

[20] A brief history of the plant is given on pp. 109-111.

its granite domes and knobs which support little or no vegetation. In the higher foothills the timber is small and scattered. As elevations decrease, however, the brush-covered areas increase, and farther west the brush disappears and hills of the lower foothill belt are bare.

Precipitation in the basin of American River probably varies from an annual mean slightly exceeding 20 inches in the lower parts of the area to about 70 inches on the headwaters of Silver Creek and the Rubicon. Over a large part of the basin the annual mean is at least 50 inches. In the high mountains of the eastern part and on the long ridges extending toward the west the greater part of the precipitation is in the form of snow. Elevations along the main divide are sufficient to hold a part of this snow until late in the summer and, after winters when the snows have been early and plentiful, into the following winter. During less favorable years all but isolated patches of snow disappear before the end of summer, even from the highest peaks. The United States Geological Survey has maintained a gaging station on American River at Fair Oaks, 7 miles below Folsom, since 1904.[21]

RESERVOIRS.

Several lakes on the headwaters of the South Fork are used for storage to increase the flow in ditch systems that supply the mining region and a small power plant above Placerville, but even when augmented by the waters thus stored the discharge of that fork becomes very small by the end of the dry season.

On the heads of Middle and North forks there are also several reservoirs of small or moderate size. The storage on all three forks is used diversely and contributes only incidentally to the power developed at Folsom.

CONDUIT.

The Folsom head dam (Pl. XXI, *B*), a massive structure of granite laid in cement mortar, crosses American River at a point 2,000 feet above the California State prison at Folsom. The crest of the dam is straight, is 525 feet long and 24 feet wide, and its elevation is 210 feet above sea level. Its maximum height is 87 feet.

Formerly a trussed timber shutter, 180 feet long and 6 feet wide, was hinged on the upstream edge of the crest so that it could be raised by a system of hydraulic pumps; when not in use it dropped into a recess on the crest of the dam. The pondage supplied by the shutter was naturally of much greater service when the plant was on an isolated system than at present, when it is but a small unit in a great network and can be run on a flat load.

---

[21] For published records see U. S. Geological Survey Water-Supply Papers as follows: 298, pp. 302-314 (Nov. 3, 1904, to June 30, 1912); 331, pp. 317-319 (Oct. 1, 1911, to Sept. 30, 1912); 361, pp. 357-359 (1912-13); 391, pp. 258-361 (1913-14); 411, pp. 270-272 (1914-15); 441, pp. 246-247 (1915-16); 461, pp. 240-242 (1916-17); 481, pp. 232-233 (1917-18).

FOLSOM PLANT, PACIFIC GAS & ELECTRIC CO.

covered for nearly their entire length. One line is of riveted steel throughout; another is of riveted steel for most of its length but has some cast-iron pipe in it; the other three are cast-iron throughout except for very short lengths at their upper ends, where there is riveted pipe one-eighth inch thick. The cast-iron pipe is in 12-foot lengths and has bell and spigot joints calked with lead; the thickness of the shell varies from one-half inch to $1\frac{1}{2}$ inches. Great care has to be used in shutting down the units on the cast-iron lines to prevent water hammer which will blow out sections of the lead calking. For about half the distance from the forebay to the power house the five lines run side by side; below the lines diverge, three running to the upper and two to the lower end of the house, one passing on each side of a low, rocky hummock. At the back wall of the house each group of pressure pipes delivers its supply to a separate header. Each line is provided with a 30-inch gate valve just before reaching the header, and on the other side of the header there is a gate valve in each supply branch to the wheels. The valves in the branches to the 2,000 kilovolt-ampere units are hydraulically operated.

The static head is 702 feet and the effective head 680 feet.

GENERATING STATION.

Power house.—The power house (Pl. XXIII, *C*), which extends along the bank of the river, is a single, very long and narrow one-story masonry building, 264 feet long and 40 feet wide, roofed with corrugated iron supported on steel trusses. The seven units are placed in line along the front of the building (Pl. XXIII, *D*), with their shafts parallel to its long axis. The three 900 kilovolt-ampere units that form the original installation are at the downstream end; next to these is the last machine installed, originally rated at 5,500 kilovolt-amperes but rewound during 1918 for a rated capacity of 6,875 kilovolt-amperes; and in the upstream end are the three 2,000-kilovolt-ampere machines which were the first material addition to the original plant. Prior to the installation of the three machines last mentioned, a single 720 kilovolt-ampere unit had been purchased to work in parallel with the Nevada plant at 133 cycles. This unit occupied the extreme upstream end of the power house but has been dismantled.

The transformers and switching equipment are arranged along the rear wall of the plant on the main floor and in a gallery supported on steel columns. The low-tension switches and busses are in a subway parallel to the rear wall running the full length of the power house. The switchboard is on the main floor parallel to the rear wall, about in the center of the room. The transfer busses are in a long gallery under the main floor. The pressure line to each wheel runs from a header straight across the power house, and the wheel discharges through an arched wasteway opening directly over the river.

Hydraulic equipment.—The three 900 kilovolt-ampere units are operated by Risdon Iron Works 67⅝-inch wheels, with two rotors per unit, both carried in the same housing, each equipped with 24 buckets and operated by a single plain deflecting 3-inch nozzle controlled by a Lombard governor, type F.

The three 2,000 kilovolt-ampere units are operated by wheels of the same type but 79 inches in diameter, and each rotor is equipped with 22 buckets and receives a stream from a single 4½-inch plain deflecting nozzle controlled by a Lombard governor, type D.

The two wheels that operate the single 6,875-kilovolt-ampere unit are of Doble design and manufacture and are of the double-overhung type, one wheel at each end of the shaft. The wheels are 59 inches in diameter and each rotor is equipped with 15 buckets. Each wheel is operated by the stream from a single 7½-inch deflecting needle nozzle controlled by a Lombard governor, type Q. The installed capacity of the plant is 15,575 kilovolt-amperes (20,878 horsepower).

Generators.—The 900 kilovolt-ampere generators are of the Stanley SKC 3-phase 60-cycle 2,300-ampere type, operating at 360 revolutions per minute.

The 2,000-kilovolt-ampere machines are of the same type, phase, and voltage but are rated at 500 amperes and operated at 240 revolutions.

The 5,500-kilovolt-ampere generator is a Westinghouse 3-phase 60-cycle 2,300-volt 1,375-ampere alternator, operating at 300 revolutions per minute.

Exciters.—Two General Electric 4-pole 60-volt 750-ampere 45-kilowatt exciters, one operated by a Risdon wheel, the other by a similar wheel or by a 50-horsepower Westinghouse induction motor, and one Northern Electric Manufacturing Co. 60-volt 500-ampere 30-kilowatt exciter direct-connected to a 40-horsepower Westinghouse induction motor furnish excitation for the entire plant.

Transformers.—The power house normally operates in two sections, one transmitting at 60,000 volts to Sacramento and Oakland and the other at 30,000 volts to the mining district around Nevada City. The station is equipped with three banks of Stanley SKC shell-type 700-kilowatt 2,300/34,675 water-cooled transformers with a spare that can be connected in emergency to any of the three banks; three Stanley SKC shell-type 1,000-kilowatt 2,300/34,675 water-cooled transformers connected Y on the high-tension side to give 60,000 volts; and three 1,500-kilowatt 2,300/34,675 water-cooled transformers also connected Y on the high-tension side to give 60,000 volts.

San Francisco. The cable laying was completed January 23, 1912, but owing to defective splices, which ruptured when it was being tested, operation was not begun until January 29.

The eastern terminus of the crossing is at the Western Pacific mole in Oakland, and the western is at Folsom Street wharf in San Francisco. At the Oakland end the cable receives power from the hydroelectric system and in San Francisco connects with the network originally operated by the City Electric Co. The total length of the cable between the ends of the two docks is 18,800 feet and the total length overall from land to land is 19,800 feet. The additional 1,000 feet on the ends is a cable specially protected to withstand injury from interference by passing vessels.

The main cable contains three 4/0 tinned conductors, each consisting of 19 strands of soft-drawn copper wire. Each conductor is encased in a rubber coating five thirty-seconds of an inch thick, which is wound with a single layer of rubber-faced tape and is finally covered with a winding of varnished cambric two thirty-seconds of an inch thick. The three separate insulated conductors of this type are wound together with a pitch of 24 inches, and the resulting cable is built up in circular form with jute filler held in shape by a winding of six thirty-seconds of an inch of varnished cambric. This winding is surrounded by a sheet of ⅛-inch lead and around this sheet there is four thirty-seconds of an inch of jute, which lies directly under the armoring of 37 No. 4 galvanized-steel wires wound with a pitch of 24 inches. Over this armoring is a cover of three thirty-seconds of an inch of tarred jute with sand and lime finish.[83] The diameter of the cable is 3.75 inches and its weight 17½ pounds per foot.

The cable has a maximum capacity of 6,200 kilovolt-amperes when submerged in water of 55° temperature. A safe maximum temperature for the cable may be considered as 130°. The cable was designed for 12,000 volts but was tested to a maximum of 32,000 volts. It is operated Y grounded.

The laying of the second 11,000-volt cable under the bay by the company was completed June 18, 1914, and laying of the third by way of Goat Island early in 1916.

BRANCH TRANSMISSION LINES.

In addition to the main tower lines described in the preceding paragraphs a short branch tower line extends from the Oakland substation northeastward into the Moraga Valley in Contra Costa County. This line is operated at 100,000 volts and is of the standard construction used on the main line.

---

[83] Naphtaly, S. D., The trans-Bay cable of the Great Western Power Co.: Jour. Electricity, p. 340, Mar. 16, 1912; p. 1, July 4, 1914 (second cable); p. 427, June 3, 1916 (third cable).

In addition to the steel tower lines several 22,000-volt branch lines run out of the Brighton, Isleton, and Cowell substations. The longest and most important of these is that which runs from Isleton westward to a point north of Suisun Bay to feed the Vallejo, Petaluma, and Santa Rosa districts. The extent of the branch lines may be seen by referring to the general transmission map (Pl. I, in pocket).

NEVADA-CALIFORNIA AND SOUTHERN SIERRAS POWER SYSTEMS, MEAN MONTHLY LOADS AND LOAD FACTORS, 1908–1921

TABLE 157.—*Power generated and purchased by The Southern Sierras Power Co., 1912–1920.*

Year.	Hydro-electric power generated.	Steam electric power generated.	Total power generated.	Power purchased.	Total power generated and purchased.	Mean load.	System peak.	System load factor.
	Kilowatt-hours.	*Kilowatt-hours.*	*Kilowatt-hours.*	*Kilowatt-hours.*	*Kilowatt-hours.*	*Horse-power.*	*Horse-power.*	*Per cent.*
1912		1,526,450						
1913	17,197,560	7,593,533	24,791,033	[a] 6,724,800	31,515,833	4,823	8,300	58.0
1914	23,175,000	1,328,220	24,503,220	[b] 23,149,386	47,652,606	7,292	10,600	68.8
1915	22,610,500	1,321,075	23,931,575	32,795,400	56,726,975	8,681	12,200	71.2
1916	57,096,000	785,950	57,881,950	332,050	58,214,000	8,884	13,500	65.8
1917	71,409,700	7,335,000	78,744,700	[c] 3,304,510	82,049,210	12,555	24,500	51.2
1918	[d] 104,960,375	6,282,900	111,243,275	[e] 1,256,650	112,499,925	17,215	28,200	61.0
1919	[f] 137,945,500	4,317,700	142,263,200	6,427,400	148,690,600	22,753	40,600	56.0
1920	136,318,250	3,300,900	136,619,150	[g] 1,841,425	141,460,575	21,588	37,800	57.1

[a] Part from Southern California Edison Co. at San Bernardino (515,200 kilowatt-hours), balance (6,209,600) from The Nevada-California Power Co.
[b] Southern California Edison Co. at San Bernardino 139,400 kilowatt-hours and The Nevada-California and Pacific Power at control 23,009,986 kilowatt-hours.
[c] Purchased at Colton and Barstow.
[d] Includes plant 2 August to November and Rush Creek for full year operated under lease.
[e] Southern California Edison Co. 623,350 kilowatt-hours, The Nevada-California Power Co. 633,300 kilowatt-hours.
[f] Includes Mill Creek plant November and December on account of plant leased by The Southern Sierras Power Co.
[g] Includes 2,300 kilowatt-hours from Green Creek.

NOTE.—Hydro power generated at plants 3, 5, and 6, Rush Creek and Blythe, and steam generated at city of San Bernardino in 1917.

TABLE 158.—*Power generated and purchased by Pacific Power Corporation, 1913–1917.*

Year.	Power generated.[a]	Power purchased.	Total.	Mean load.	System peak.
	Kilowatt-hours.	*Kilowatt-hours.*	*Kilowatt-hours.*	*Horse-power.*	*Horse-power.*
1913	6,235,071	[b] 271,920	6,506,991	996	
1914	8,320,350	2,313,440	10,633,790	1,627	4,000
1915	7,530,930	6,462,030	13,992,960	2,141	4,420
1916	12,070,400	3,643,160	15,713,560	2,398	3,350
1917	[c] 6,200,150	2,006,400	8,314,550	3,075	

[a] All hydro, no steam plants operated.
[b] Purchased from The Nevada-California Power Co. in December.
[c] Jan. 1 to May 31, 1917, when system was taken over by the Nevada-California Power Co.

Daily load curves for The Nevada-California system, including all companies operated and leased at the date of the curves, are shown in figure 38. Separate curves for Pacific Power Corporation prior to its acquisition by The Nevada-California system are shown in figure 39. In the latter curves power purchased was received from The Nevada-California Power Co. (See also fig. 40.)

Growth in number of consumers for The Nevada-California Power Co. is shown in Table 159, for The Southern Sierras Power Co. in Table 160, and for Pacific Power Corporation up to the year of its acquisition by The Nevada-California Power Co. in Table 161.

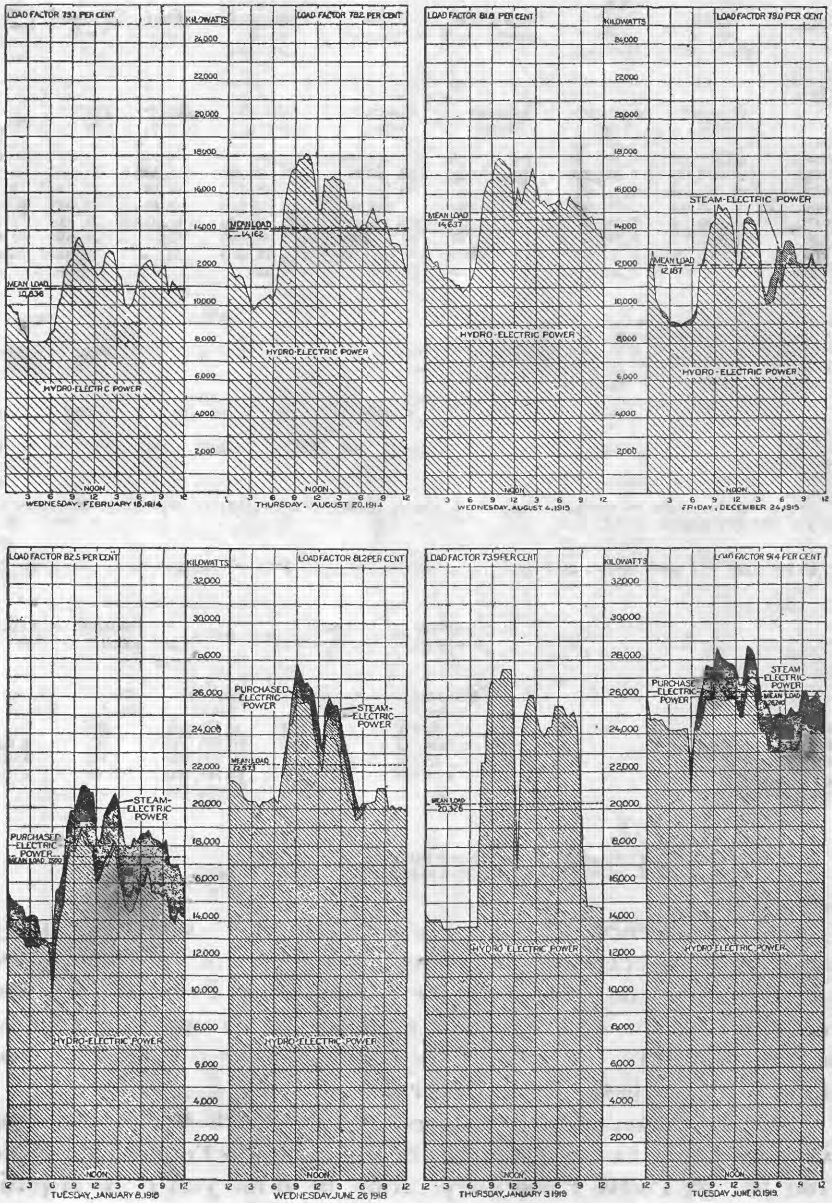

Figure 38.—The Nevada-California Power

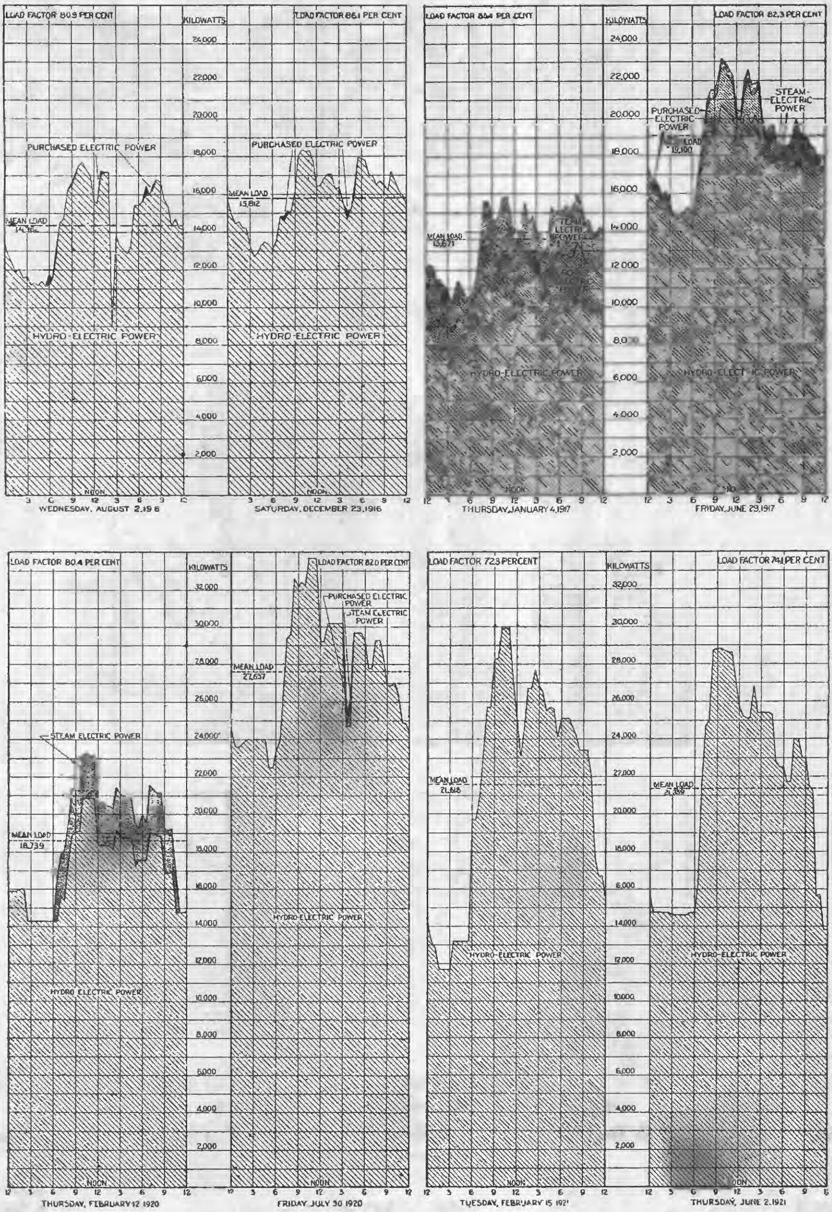

system, daily load curves, 1914–1921.

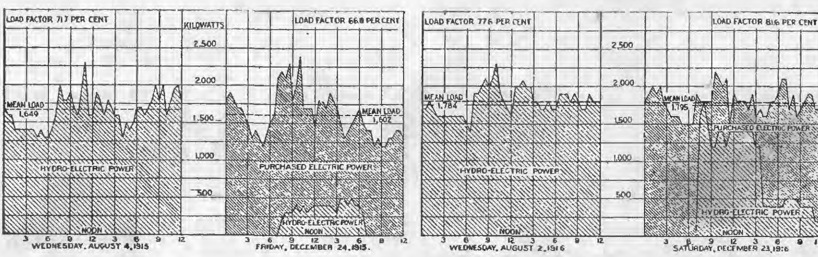

FIGURE 39.—The Nevada-California Power system (Pacific Power Corporation), daily load curves, 1915-16.

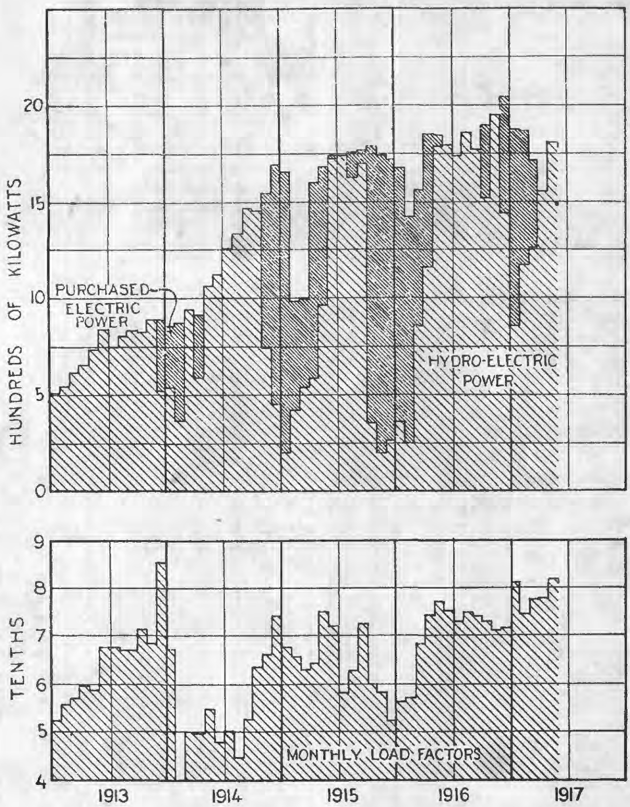

FIGURE 40.—Pacific Power Corporation, mean monthly loads and load factors from 1913 to date of absorption by The Nevada-California Power system.

TABLE 159.—*Growth in number of consumers on the system of The Nevada-California Power Co.*

	Consumers.		Consumers.
1908	1,305	1915	2,500
1909	1,849	1916	2,594
1910	1,935	1917	2,400
1911	1,960	1918	1,907
1912	2,089	1919	2,111
1913	2,095	1920	2,029
1914	2,429

HYDROELECTRIC SYSTEM OF SIERRA PACIFIC ELECTRIC CO.

How temperature varied in two dams while the cement was setting, by R. A. Monroe: Eng. News Rec., vol. 79, No. 6, p. 253, Aug. 9, 1917. Tabular data on the temperatures developed in the setting concrete of the Spaulding and Rock Creek dams of the South Yuba-Bear River system. 1,500 words; 1 photograph; 2 diagrams; 2 tables.

The putting in of the Wise power plant: Jour. Electricity, vol. 38, No. 6, p. 196; Mar. 15, 1917. Short description of the South Yuba-Bear River system, and the ceremony of putting the Wise plant into operation. 1,000 words; 4 photographs.

Experience with high-head Francis turbines, by J. P. Jollyman: Jour. Electricity, vol. 38, No. 8, p. 275, Apr. 15, 1917. General statement of the results obtained by Pacific Gas & Electric Co. in the operation of high head Francis turbines. 1,000 words; 2 photographs; 1 map.

Unusual details in power-house installation, by J. P. Jollyman: Jour. Electricity, vol. 38, No. 9, p. 321, May 1, 1917. An account of some of the economies effected in the design of the Wise and Halsey power houses, and an outline of certain construction methods. 2,500 words; 4 photographs.

Rock Creek multiple arch dam, by R. A. Monroe: Jour. Electricity, vol. 38, No. 11, p. 421, June 1, 1917. A general outline of the South Yuba-Bear River system, with a detailed description of Rock Creek dam. 1,500 words; 3 photographs; 1 map; 2 structural details.

Three major power possibilities in California, by F. H. Fowler: Jour. Electricity, vol. 41, No. 1, p. 12, July 1, 1918. A comprehensive statement of the growth in demand for power in California and a description of the proposed developments at Big Bend of the Pit, Feather River site No. 5, and on Big Creek of the San Joaquin. 3,000 words; 7 photographs; 7 diagrams.

Construction of a unique power plant: Jour. Electricity, vol. 39, No. 9, p. 392, Nov. 1, 1917. A description of the Spaulding power house of the South Yuba power system. 100 words; 4 photographs; plan and elevation; map of system.

Spaulding power plant completed, by J. P. Jollyman: Pacific Service Mag., vol. 9, No. 8, January, 1918. A concise description of this installation by its designer. 1,500 words; 7 photographs.

Double overhung Francis turbines, by Arnold Pfau: Jour. Electricity, vol. 40, No. 6, p. 279, Mar. 15, 1918. A discussion of this type of prime mover, illustrated by notes on White Salmon River and Halsey plants. 750 words; 4 photographs; plan; elevation and diagram map.

Interconnection and new power development, by P. M. Downing: Jour. Electricity, vol. 40, No. 6, p. 282, Mar. 15, 1918. A discussion of the effect of State and Federal regulation on power development; the relation of such regulation to the threatened fuel shortage; and the estimated power demands on the systems serving central California up to 1921. 2,000 words; 1 diagram.

Hydroelectric economies, by J. P. Jollyman: Jour. Electricity, vol. 40, No. 8, p. 384, Apr. 15, 1918. Details of efficiency tests of the pipe lines, water wheels, generа[illegible]nsformers, and entire installations at Drum, Wise, and Halsey plants. 1,800 [illegible] 4 photographs; 1 elevation; 1 tabulation.

[illegible]lowatt-hours per barrel of oil. What does it mean? by S. J. Lisberger: Jour. Electrici[illegible], vol. 42, p. 363, Apr. 15, 1919. Discussion of varying operating conditions, to show that "kilowatt-hours per barrel of oil" means nothing unless properly qualified. 2,500 words..

Note.—Pacific Service Mag.: In June, 1909, Pacific Gas & Electric Co. began the publication of a monthly magazine. The volumes which have appeared have contained many valuable illustrated descriptions of the company's system.

NORTHERN CALIFORNIA POWER CO. CONSOLIDATED.

[Absorbed by Pacific Gas & Electric Co. Oct. 3, 1919.]

Northern California Power Co.'s transmission: Jour. Electricity, vol. 12, p. 231, 1902. Description of first station at Volta, Kilarc plans, and transmission system. 4,000 words; 15 photographs.

Northern California Power Co.'s systems, Part 1. Electrical World, vol. 44, 1904; p. 407, Sept. 10. A detailed description of the first development at Volta. 3,500 words; 7 photographs, and 1 diagrammatic map.

Idem, Part 2. Electrical World, p. 455, Sept. 17. Detailed description of the Kilarc system. 6,000 words; 7 photographs; 1 diagrammatic map, 4 details and wiring diagrams.

Idem, Part 3. Electrical World, p. 503, Sept. 24. Detailed description of transmission system. 3,600 words; 5 photographs; 1 diagrammatic map.

Idem, Part 4. Electrical World, p. 559, Oct. 1. Detailed description of the dredges operated at Horsetown. 3,800 words; 2 photographs.

The water power plants of Northern California Power Co. Eng. Rec., p. 506, Oct. 29, 1904. An abridgment of the continued article beginning in the Electrical World of Sept. 10. This article covers the Volta and Kilarc stations, but does not give full data on transmission lines. 2,700 words; 5 photographs.

Northern California Power Co. Consolidated, by Rudolph W. Van Norden: Jour. Electricity, vol. 25, p. 5, Aug. 6, 1910. A minute description of the system. 11,150 words; 57 photographs; 1 general map; ground plans of Volta and Inskip; 5 details; and a tabulation of engineering and transmission data.

The Coleman plant, by R. W. Van Norden: Jour. Electricity, vol. 27, p. 411, Nov. 4, 1911. A detailed description of the plant and features of its construction, by its designer. 6,500 words; 24 photographs; and a map of the conduit line.

The Coleman hydroelectric development on Battle Creek, Calif.: Eng. Rec., vol. 64, p. 700, Dec. 16, 1911. Complete description of the Coleman hydraulic system, with short outline of the power house and its equipment. 3,000 words; 8 photographs; 1 map.

New hydroelectric plant of Northern California Power Co., by Rudolph W. Van Norden: Electrical World, vol. 59, p. 237, Feb. 3, 1912. General description of the four other Battle Creek plants of the system, and a detailed description of the Coleman plant. 2,500 words; 8 photographs; 1 map.

Pumping plants for rice irrigation, by C. F. Adams: Jour. Electricity, vol. 37, p. 117, Aug. 12, 1916. Description of an installation with a motor capacity of 950 horsepower. 1,000 words; 4 photographs; 1 map.

SIERRA & SAN FRANCISCO POWER CO., COAST VALLEYS GAS & ELECTRIC CO., AND SUBSIDIARIES.

The Bryant street steam plant: Jour. Electricity, vol. 4, p. 61, July, 1897. A history and general description of this plant. 2,000 words; 6 photographs; 3 plans and elevations.

The Monterey and Pacific Grove lighting plants, by Harry J. Bean: Jour. Electricity, vol. 7, p. 37, 1899. Description of equipment in first lighting plant in Monterey. 1,800 words; 6 diagrams.

The United Railroads of San Francisco: Jour. Electricity, vol. 14, p. 33, 1904. Description of system in general, and of original North Beach steam plant in detail. 6,500 words; 16 photographs; 10 plans; elevations; 1 map.

Electric-power development on Stanislaus River: Jour. Tech., p. 26, August, 1908. A general description of the Stanislaus plant. 1,200 words; photographs of diverting dam and power house.
