

MISCELLANEOUS ANALYSES OF COAL SAMPLES FROM VARIOUS FIELDS OF THE UNITED STATES.

INTRODUCTION.

In connection with the examination of various coal fields of the United States during the year 1912 a large number of coal analyses were made for the purpose of determining the value of the land underlain by the particular coal bed sampled, in case the land is a part of the public domain, and also to furnish information to the general public concerning the fuel resources of the country, regardless of whether the coal is in the public domain or in lands of private ownership.

Most of these analyses will be published in the descriptions of the fields to which they pertain, but such reports are necessarily delayed until all the data gathered in the field have been thoroughly digested, and consequently they may not appear for several months or even a year. In order, however, to make the analyses immediately available they have been grouped and are inserted here in advance of the appearance of the reports to which they relate. On account of this method of publication it is impossible to describe the samples adequately and to discuss and compare the analyses, but it is believed that enough data are given to make them intelligible, and it is to be hoped that their value to the public in general will be such as to warrant advance publication.

Many of the samples were collected during the survey for classification of some of the western fields where mining has not been begun or has attained so slight a development as to render it negligible. In these fields it is difficult, if not impossible, to secure fresh material, and hence the analyses show the coal to be of lower than its actual grade. Therefore these analyses should be taken with considerable allowance, and no important development should be based upon them until they have been verified or disproved by the analyses of freshly mined coal. The analyses of weathered samples are of value only until they can be supplanted by more reliable results.

In taking a sample of coal for analysis the geologist is instructed to make every endeavor to procure fresh unweathered material. He is supposed to face up the bed in the mine or prospect until fresh

material is available, and then to obtain his sample by making a uniform cut across the bed from roof to floor, including all such benches and partings as an experienced and careful miner would include in commercial coal and throwing out such impurities as would certainly be excluded in practical operation. He is supposed to cut sufficient coal to give at least 6 pounds per foot of coal bed sampled. The sample is hastily pulverized in the mine until it will pass through a $\frac{1}{2}$ -inch mesh, and then is quartered down until about 4 pounds remain. This is placed in a galvanized-iron can, sealed with adhesive tape or paraffin, and mailed to the laboratory for analysis. The sampling is done on the principle that a coal mine should be sampled as carefully as a gold mine and that the sample should be even more carefully handled after it has been taken. The object of sealing is to prevent change in the moisture content, so that the coal may reach the laboratory in practically the same condition that it exists in the mine. Coal is a very unstable substance, and great care must be exercised to prevent oxidation in the course of preparation and in transit. It is also important that the sample should consist of neither the best nor the poorest coal, but that it should be representative of the output of the mine, if one is in operation, or, if the field is undeveloped, it should represent as nearly as possible the merchantable coal that may be secured at some time in the future when mining is carried on.

Although the aim of the geologist in obtaining a sample by the method specified above is to obtain coal that is representative of the output of the mine, practical experience has shown that this is seldom or never accomplished. Almost invariably the sample obtained in the mine contains a lower percentage of impurities than does the coal which reaches the consumer. This is largely due to carelessness in mining and handling and probably could be largely eliminated were the conditions of mining more nearly ideal. By comparing a large number of samples taken in a mine with those taken at the point of consumption it has been found that there is a fairly constant though small difference in the percentage of moisture, ash, and sulphur, and that almost invariably the amount of these substances in the mine sample is less than it is in the merchantable coal. For this reason a small amount should be added, especially to the ash given in the accompanying table, to correctly represent the ash in merchantable coal from the same mine.

During the early stages of land classification all the analytical work was done by the Geological Survey, but with the establishment of a Bureau of Mines "the analyzing and testing of coals, lignites, and other mineral-fuel substances" of the United States passed by law to that bureau. Accordingly all the coal analyses listed in this paper are credited to the Bureau of Mines. Although the analytical work has passed from one bureau to another, the laboratory and

many of the chemists in the work have remained the same and consequently the results are strictly comparable.

In the table, the analyses are given in four forms, marked A, B, C, and D. Analysis A represents the sample as it comes from the mine. This form is not well suited for a comparison of one coal with another because the amount of moisture in the sample as it comes from the mine is largely a matter of accident, and consequently analyses of the same coal expressed in this form may vary as widely as the analyses of coal from different beds or from different fields. Analysis B represents the sample after it has been dried at a temperature a little above the normal until its weight becomes constant. This form of analysis probably presents the coal in its most stable condition and one approaching most closely its condition as it reaches the market. Therefore it is the form best adapted to the general purposes of comparison. Analysis C represents the theoretical condition of the coal after all the moisture has been eliminated. Analysis D represents the coal after all moisture and ash have been theoretically removed. This is supposed to represent the true coal substance, free from the most significant impurities. Forms C and D are obtained from the others merely by recalculation. They should not be used in comparison, for they represent theoretical substances that do not exist.

In the analytical work it is not possible to determine the proximate constituents of coal or lignite with the same degree of accuracy as the ultimate constituents. Therefore the air-drying loss, moisture, volatile matter, fixed carbon, and ash are given to one decimal place only; whereas the ash (in the ultimate analysis), sulphur, hydrogen, carbon, nitrogen, and oxygen are given to two decimal places. The determination of the calorific value to individual units is not reliable, hence in the column headed "Calories" the values are given to the nearest five units and in the column headed "British thermal units" they are given to the nearest tens, as the value of a British thermal unit is about one-half that of a calorie.

CLASSIFICATION OF COAL.

The classification of coal into various grades, such as bituminous, semibituminous, and lignite, is arbitrary and not at all satisfactory, but it is in common use in the United States and it seems desirable to give the class for each sample, because from the analysis one could not always determine this important point. The classes generally used in the United States are as follows: Anthracite, semianthracite, semibituminous, bituminous, subbituminous, lignite.

Anthracite.—This coal is generally well known, but in a systematic classification it is generally defined as a hard coal having a fuel ratio

(fixed carbon divided by volatile matter) of not less than 10. Most of this coal comes from the anthracite fields of western Pennsylvania, but small areas are known in some of the Western States where the coal has been changed to anthracite by the heat and pressure of masses of igneous rock.

Semianthracite.—This class of coal has a fuel ratio ranging from 6 to 10. There is only a small amount of this coal in the United States, found in local basins or in close proximity to igneous rocks.

Semibituminous.—This class is of great commercial importance, but is not widely distributed. Its fuel ratio ranges from 3 to 6. It is the best steam coal in the country, and some of it can be utilized in the manufacture of coke. The centers of production are the Pocahontas and New River fields of Virginia and West Virginia, Georges Creek field of Maryland, Clearfield field of Pennsylvania, and the western end of the Arkansas field in the vicinity of Fort Smith. Though small areas containing this grade of coal have been found in Washington and Colorado, the amount of coal in these fields is small.

Bituminous.—This is the most important grade of coal in the country and includes most of the coals east of the Rocky Mountains. In the Western States there are large areas of bituminous coal, such as the Trinidad-Raton field of Colorado and New Mexico; the Grand Hogback field of Colorado; the Book Cliffs field of Utah, Rock Springs, Kemmerer, and Black Hills fields of Wyoming; the Great Falls field of Montana; and many districts of Washington. This grade furnishes most of the coking coal of the country, and it is largely sold for steam raising and domestic use.

Subbituminous.—The term "subbituminous" has been adopted by the Geological Survey for what has generally been called "black lignite." The latter term is objectionable, for the reason that the coal is not lignitic in the sense of being woody, and the use of the term seems to imply that the coal is little better than the brown, woody lignite of North Dakota, whereas many of the coals of this class closely approach the lowest grade of bituminous coal. In fact, it is extremely difficult to separate this class from the one below and the one above. It is generally distinguished from the lignite by its color and freedom from apparent woody texture and from bituminous coal by the slacking it undergoes when exposed to the weather. As the latter is an important difference in commercial use, it has been adopted by the Geological Survey as a criterion for the separation of subbituminous and bituminous coals.

Subbituminous coal is found in most of the western fields, being well known in the field about Boulder and Denver and in North Park, Colo.; Gallup, N. Mex.; Hanna, Douglas, Sheridan, and the Bighorn Basin, Wyo.; Red Lodge and Musselshell, Mont.; and in many of the districts of Washington and Oregon.

Lignite.—As used by the Geological Survey this term is restricted to the coals that are distinctly brown and generally woody. They are intermediate in quality between peat and subbituminous coal. Lignite is abundant in the North in eastern Montana and North Dakota and in the northwest corner of South Dakota. In the South it is present in all of the Gulf States, but it has been developed commercially only in Texas.

papers on.....	9-90
Olive Creek, Okla., oil development on.....	37
Oklahoma, north-central, geologic work in.....	27-28
geology of.....	30-34
oil and gas development in.....	27-53
map showing.....	52
oil in, development of.....	35-53
occurrence of.....	34
quality of.....	36
oil sands in.....	31-32
structure of.....	33
topography of.....	28-29
Omera, N. Mex., coal near.....	293
Ophir, Mont., coal near.....	243
Ordovician rocks, distribution of, in Kentucky, map showing.....	10
occurrence and character of.....	15
Oregon, coals of, analyses of.....	348-349
Ortiz Arroyo, coal in.....	310
section in.....	310
Oseola, Pa., gas well near.....	88

P.

Pardee, J. T., on coal in Tertiary lake beds, Montana.....	229-244
Patton quadrangle, structure of, map showing.....	86
<i>See also</i> Pennsylvania, central.	
Pawnee, Okla., oil development near.....	41
Payette formation, coal in.....	243
occurrence and character of.....	247-248
Paynter, W. B., work of.....	10
Peale, A. C., work of.....	54
Peck, F. B., work of.....	71

	Page.
Pennsylvania, cooperation of.....	69, 70
coals of, analyses of.....	348-349
oil and gas in.....	69-70
Pennsylvania, central, faults in.....	82-84
faults in, type of, figure showing.....	83
folds in.....	74-82
gas sands in.....	84-85
structure of.....	85-86
geologic structure in.....	69-90
map showing.....	86
representation of.....	71-73
wells in, for gas.....	84-88
for gas, record of.....	87-88
for water.....	88-89
sections of, figure showing.....	88

Pennsylvanian rocks, distribution of, in Kentucky, map showing.....	10
occurrence and character of.....	18
Perry, Okla., oil wells near.....	51
Petroleum and natural gas, papers on.....	9-89
Phalen, W. C., work of.....	71
Ponca, Okla., oil development near.....	32,
	34, 44-47, 52-53

Pottsville formation, occurrence and character of.....	18
Punxsutawney quadrangle, structure of, map showing.....	86
<i>See also</i> Pennsylvania, central.	
Punxsutawney syncline, location and character of.....	81-82

R.

Ragland oil field, Ky., field work in.....	10
geology of.....	11-21
history of.....	9-10
location of, map showing.....	10
map of.....	20
oil sands in.....	16
structure of.....	18-21
paper on.....	9-26
prospecting in, guides for.....	21
topography of.....	11
utilization of.....	26
wells in, records of.....	14
records of, figure showing.....	20
Ralston, Okla., oil development near.....	34, 43-44, 52
Red Rock, Okla., oil wells near.....	52
Richardson, G. B., work of.....	54
Ripley, Okla., oil development near.....	37-38
Rogers, G. S., on Little Sheep Mountain field, Mont.....	159-227
Rogers, N. Mex., coal near.....	294
section near.....	294
Rothwell, Ky., gas near. <i>See</i> Menifer gas field.	

S.

Scope of volume.....	7
Semianthracite, definition of.....	334
Semibituminous, definition of.....	334
Silurian rocks, distribution of, in Kentucky, map showing.....	10
occurrence and character of.....	15
Sloan, A. H., work of.....	160
Soper, E. K., work of.....	92
South Dakota, coals of, analyses of.....	348-349

	Page.		Page.
Stanton, T. W., fossils determined by . . .	94-95, 168	"Waverly formation," occurrence and character of . . .	17-18
Stillwater, Okla., oil development at . . .	38	Wegeman, C. H., on Barber coal field, Wyo. . .	263-284
Stone, R. W., work of . . .	266	West Virginia, coals of, analyses of . . .	352-353
Structure, importance of . . .	69	Willet, gas near . . .	88
representation of . . .	71-73	Williston lignite field, N. Dak., access to . . .	91
<i>See also particular localities, fields, etc.</i>		geology of . . .	93-96
Structure contours, use of . . .	71-73	lignite of, character of . . .	97-103
Subbituminous, definition of . . .	334	development of . . .	103-104
		by townships . . .	106-158
