SPIRIT LEVELING IN VERMONT, 1896–1935

J. G. STAACK, Chief Topographic Engineer

INTRODUCTION

Scope of report.—This bulletin contains the results of all spirit leveling in Vermont done by the United States Geological Survey, including those heretofore published.1 The points for which figures of elevation are given are listed according to the quadrangles in which they occur, and thus the list for each quadrangle includes all points within its boundaries for which these figures have been determined. Following the quadrangle lists, which are arranged alphabetically, is a table in which are listed the positions and figures of elevation of certain points that serve to mark the Vermont-New Hampshire boundary. These points were selected and marked by a special commissioner appointed by the Supreme Court of the United States. Results of spirit leveling other than that done by the Geological Survey, with the exception of those contained in the above-mentioned table, are not included in this bulletin.

Cooperation.—Several quadrangles in the southern part of Vermont were mapped by the United States Geological Survey in cooperation with the State before 1896, the year in which the Federal Survey was authorized to establish benchmarks. Since that time the State, through its cooperating agencies, has contributed financially to the survey of 20 additional quadrangles. The War Department has also cooperated in the work, having contributed funds toward the survey of seven of the nine quadrangles that lie along the boundary between the United States and Canada, namely, Averill, Enosburg Falls, Indian Stream, Irasburg, Island Pond, Jay Peak, and Memphremagog. In 15 other quadrangles the leveling was done by the United States Geological Survey without cooperation from any other organization.

Classification of leveling.—Spirit leveling is classified according to the degree of refinement in the instruments and methods used and according to the closure errors.

First-order leveling consists of leveling done with the most improved instruments, all sections being leveled twice, in opposite directions, under varying conditions. Closures are not allowed to exceed the amount in feet represented by the formula $0.017 \sqrt{\text{length of section in miles}}$. All corrections for rod error, temperature, and unbalanced sights are applied, as well as the orthometric corrections for convergence toward the poles of level surfaces of different elevations.

Second-order leveling, according to regulations of the United States Geological Survey, comprises lines leveled twice with reliable instruments, though not necessarily of the most improved type. Closures are not allowed to exceed $0.035 \sqrt{\text{length of section in miles}}$.

Third-order leveling is made up of lines that are run, either with first-order equipment or with an engineer's wye level and rods of the New York type, in single-line circuits that are required to close within the limits, in feet, of $0.05 \sqrt{\text{length of circuit in miles}}$. This is equivalent to $0.071 \sqrt{\text{length of section if the line is leveled twice}}$.

All leveling done by the United States Geological Survey in Vermont is of third-order accuracy except as otherwise stated.

Adjustments.—The adjustment of a net of leveling begins with the first-order lines. Most of these lines in both the United States and Canada have already been combined in a general net, and the orthometric differences derived from the observed values by correction for the convergence of level planes toward the north have been adjusted to remove accidental closure errors by the mathematical method known as least squares. The latest adjustment of this kind was made in 1929 by the United States Coast and Geodetic Survey and is known as the "1929 general adjustment of first-order leveling." This adjustment included the first-order lines in Vermont, and the elevations thus derived are the fundamental references for elevations determined by second- and third-order nets. The third-order leveling of the United States Geological Survey in Vermont has been adjusted by determining weighted mean elevations for new junction points and prorating the errors of each link. The weights are taken as the reciprocals of lengths of links. The third-order net has thus been brought into agreement with the best information available for the results of the fundamental first-order leveling, although the published figures of elevation may be changed slightly by future adjustments of the level net.

Benchmarks.—The benchmarks used by the United States Geological Survey (pl. 1) are of two general classes—principal and supplementary. Principal benchmarks are placed at more or less regular intervals along a level line and are established with the aim of making them as nearly permanent as practicable. They are usually bronze

or aluminum tablets, iron posts, or copper bolts. Supplementary or auxiliary benchmarks are less formal in design and are placed between the principal benchmarks. Some of the supplementary benchmarks in common use are copper nails fitted with washers, spikes, and marks cut with a chisel on rock or masonry.

The tablets are circular in shape, measure 3 3/8 inches in diameter, and taper from a thickness of three-eighths of an inch at the center to about a quarter of an inch near the rounded edge. During a short period in the earlier years of the Survey's leveling the tablets set were made of aluminum. The softness of this metal, however, made them susceptible to damage, so that aluminum as a material for tablets was soon discarded. The earliest tablets set and those now being placed are made of bronze, and bronze is the material now specified for standard tablets. Each tablet is cast with a 3-inch shank extending from the center of its reverse side, by means of which it is cemented in place, and each bears an inscription on its face. The inscriptions on the tablets already placed differ in many details, because of changes in design at various times. The face of every tablet, however, is cast with the words “U. S. Geological Survey”; a cross at the center, which indicates the fiducial point for position or elevation; and the words “Elevation above sea.” On some tablets the inscription indicates that they were set in connection with a project in which a State or other organization cooperated; on some the inscription includes a triangle, which signifies a located point, enclosing the cross at the center. Tablets bearing a triangle enclosing a cross may be used not only as benchmarks but also as triangulation- or traverse-station marks. The inscription on most of the tablets already set includes the warning “250 dollars fine for disturbing this mark”, but the latest design omits this phrase and adds the sentence “For information write the Director, Washington, D. C.”

If the tablet is to mark a transit-traverse station, the traverseman stamps it with letters indicating this use of it, such as “Prim. Trav. Sta.”, “P. T. S.”, or “T. T.”, as well as his own identifying letter or letters, the serial number of the station, and the year, using steel dies. If the tablet is set as a benchmark, the levelman stamps it with his identifying letter or letters, the serial number, and the year. He may at the same time stamp upon it with steel dies the figures of elevation to the nearest foot, or these figures may be added later. Tablets that serve as benchmarks may have been set as such, or they may have been set to mark traverse stations. Thus many of them serve a dual purpose, but each has stamped upon it the date and the identifying designation of the engineer who established it.

The figures of elevation that appear on a tablet are usually those determined by field computation only. It is sometimes found, therefore, that they do not represent the latest information. This has
happened either because they refer to some independent datum temporarily adopted before first-order trunk lines made standard datum available, or because a later adjustment made in the office has rendered necessary an appreciable change in the figures as determined in the field. It is assumed that engineers and others who require accurate figures of elevation for the marks will use those printed in a bulletin such as this one, instead of accepting the stamped figures. If the appropriate bulletin is not conveniently accessible, a request for the desired information may be addressed to the Director of the United States Geological Survey, Washington, D. C.

The tablets, of whatever style, are cemented into holes drilled in solid rocks or in the walls of public buildings, bridge abutments, or other masonry structures. Where masonry or rock is not available the tablets are set in the tops of reinforced concrete posts, which may be either precast or mixed and molded at the selected site. The posts are about 8 inches square or 8 inches in diameter at the top and larger at the base. They are generally so set as to project about 6 inches above ground and are made sufficiently long to reach below the frost line.

Antedating the concrete posts which are now constructed to hold the tablets in places where masonry or rock is not available are wrought-iron posts, to whose tops are riveted bronze caps of similar design to the tablets. These iron posts measure 4 feet in length and 3½ inches in outer diameter and are set about 3 feet in the ground. The bottom of the post spreads out to a width of about 10 inches in order to give it a firm footing in the earth. No iron posts have been set in recent years. They have proved impracticable, as they are easily disturbed and are subject to rust at the ground level, which eventually destroys them.

The third form of principal benchmark, set only in the early leveling, is a copper bolt, designed to be wedged into a drill hole in rock or masonry and perhaps further secured with lead or cement. This bolt is 4 inches in length and 1 inch in diameter and has a slot at one end into which fits a brass wedge. The wedge serves to expand the bottom end of the bolt, so that after the bolt has been driven to almost its full length into the hole, it cannot be easily removed. The exposed end of the bolt bears an appropriate inscription, stamped upon it with steel dies. This inscription is made up of the letters "U S G S", the letters indicating the datum used, the abbreviated word "Ft.", and the figures of elevation.

Supplementary benchmarks are of many kinds. One kind consists of a copper nail 1½ inches long supplied with a copper washer seven-eighths of an inch in diameter, through which the nail is driven into the root of a tree or some timber structure or cemented into rock after bending the point. The designation "U S G S B M" is stamped
on each washer, and on some washers the abbreviation of the name of the cooperating State is added. Another kind of supplementary benchmark is a chiseled square, used on the horizontal surface of rocks or masonry structures, or a chiseled cross, used on a vertical surface. Nails, track spikes, small capped iron pipes, and, occasionally, easily described and recognized points, such as doorsills and tops of hydrants, also serve as supplementary benchmarks.

*Preservation and restoration of benchmarks.*—Any person who finds that a principal benchmark has been damaged, disturbed, or destroyed or that it should be reset or redescribed on account of highway or other improvements will render a public service by communicating the facts to the Director, United States Geological Survey, Washington, D. C., before taking any action affecting the location or elevation of the mark. A proper form, accompanied by a return-addressed, franked envelope, will be sent for use in reporting the action taken and in recording the revised description of the mark, if any, and the notes made in obtaining the revised elevation.

*Datum.*—All elevations determined by the United States Geological Survey and those determined by the United States Coast and Geodetic Survey for inland mapping are referred to mean sea level, which is the level that the sea would assume if the influence of winds, tides, and currents were eliminated. This level is not the elevation determined from the mean of the highest and lowest tides, nor is it the half sum of the mean of all the high tides and the mean of all the low tides, which is called the half-tide level. *Mean sea level is the average height of the water, all stages of the tide being considered.* It is determined from observations made by means of tidal gages placed at stations where local conditions, such as those due to long, narrow bays, rivers, and like features, will not affect the height of the water. To obtain even approximately correct results these observations must extend over at least one lunar month, and if accuracy is desired they must extend over several years. At ocean stations the half-tide level and the mean sea level usually differ but little. It is assumed that there is no difference between the mean sea levels determined from observations made in the Atlantic Ocean, the Gulf of Mexico, and the Pacific Ocean.

*Index map.*—The accompanying index map of Vermont (fig. 1) shows the relative position of the quadrangle areas that make up the State, each of which measures 15 minutes in latitude by 15 minutes in longitude. Maps of many of the quadrangles may be purchased at 10 cents each retail or 6 cents wholesale (in lots of 50 or more). Prepayment is required and may be made by money order, payable to the Director of the United States Geological Survey, or in cash—

The heavy black lines on the index map indicate the routes of the third-order lines of leveling in Vermont run by the United States Geological Survey. The light dashed lines indicate the routes followed by the first- and second-order leveling of the United States Coast and Geodetic Survey.

**Personnel.**—The leveling of the U. S. Geological Survey in Vermont was done under the supervision of the several chief geographers or chief topographic engineers who were in administrative charge of the topographic branch during the years when the lines were run. The name of the levelman who ran a particular line and the date when it was run immediately follow the designation of the route of that line and form part of the heading that precedes the descriptions of benchmarks. The adjustment of the third-order level net and the revision, correlation, and compilation of the descriptions and elevations of benchmarks, as well as the assembling of the lists, were done mainly by D. H. Baldwin, geodetic engineer, under the supervision of R. M. Wilson, chief of the section of computing, under the general direction of J. G. Staack, chief topographic engineer.

1 The elevation of the center line of the road at a point opposite this tablet is 1,919.5 ft.
2 The elevation of the center line of the road at a point opposite this tablet is 770 ft.
3 Elevations are based upon the 1929 general-adjustment elevation, 108.022 feet, for the Chapman benchmark at Rouses Point, N. Y., and determined by means of information received in February 1906 from Prof. Arthur D. Butterfield, of the University of Vermont. The corresponding elevation of the zero of gage at Fort Montgomery, N. Y., is taken as 93.052 feet by leveling done in 1898-99 under the direction of the Deep Waterways Commission, and the corresponding elevation of the zero of gage at Burlington, Vt., is taken as 92.952 feet by using a mean of selected comparisons of gage readings at Fort Montgomery, N. Y., and Burlington, Vt., made in June 1904 by Prof. Butterfield and Prof. H. K. Barrows. Adding to this a small correction of +0.024 foot on account of flow and convergence of level planes to the north gives the accepted elevation for the zero of the Burlington gage, which is 92.976 feet.

VERMONT-NEW HAMPSHIRE BOUNDARY MARKS, 1934-36

The figures of elevation here given are taken from the report of Samuel S. Gannett, special commissioner appointed in 1934 by the Supreme Court of the United States to locate and mark the boundary between the State of Vermont and the State of New Hampshire at certain specified points. See "Supreme Court of the United States, October term, 1936, No. 2, Original (290 U. S. 579)." These figures are referred to mean sea level and are based on the 1929 general adjustment of leveling in the United States.

The initial point of Mr. Gannett's survey is a copper bolt in the Mud Turtle monument, the common corner of Vermont and New Hampshire on the north line of Massachusetts. The other marks are tablets, set either in monuments established for this purpose or in already existing substantial structures located on or near the State line as here designated. In the column headed "Mark no." the figures preceded by an asterisk indicate that the marks so designated are set on the actual State line; these are known as line-mark tablets. Marks not so designated are known as reference tablets. The positions of the marks are given in terms of latitude and longitude based on the 1927 North American datum.

SUPPLEMENTAL ELEVATIONS

The table below shows altitudes of well-known features in Vermont, such as summits, water surfaces, and tops of rails at railroad stations, as assembled from the topographic maps of the Geological Survey and from other sources. These altitudes, with the exception of a few which were determined by spirit leveling along railroads, were obtained by barometric and vertical-angle measurements. The figures given are in accord with the latest information, but they are only approximate and should not be used for accurate work.
