## AVAILABILITY OF BOOKS AND MAPS OF THE U.S. GEOLOGICAL SURVEY

---

Instructions on ordering publications of the U.S. Geological Survey, along with prices of the last offerings, are given in the current-year issues of the monthly catalog "New Publications of the U.S. Geological Survey." Prices of available U.S. Geological Survey publications released prior to the current year are listed in the most recent annual "Price and Availability List." Publications that may be listed in various U.S. Geological Survey catalogs (see back inside cover) but not listed in the most recent annual "Price and Availability List" may be no longer available.

Order U.S. Geological Survey publications **by mail** or **over the counter** from the offices given below.

### BY MAIL

#### Books

Professional Papers, Bulletins, Water-Supply Papers, Techniques of Water-Resources Investigations, Circulars, publications of general interest (such as leaflets, pamphlets, booklets), single copies of Earthquakes & Volcanoes, Preliminary Determination of Epicenters, and some miscellaneous reports, including some of the foregoing series that have gone out of print at the Superintendent of Documents, are obtainable by mail from

**U.S. Geological Survey, Information Services  
Box 25286, Federal Center, Denver, CO 80225**

Subscriptions to periodicals (Earthquakes & Volcanoes and Preliminary Determination of Epicenters) can be obtained **ONLY** from the

**Superintendent of Documents  
Government Printing Office  
Washington, DC 20402**

(Check or money order must be payable to Superintendent of Documents.)

#### Maps

For maps, address mail orders to

**U.S. Geological Survey, Information Services  
Box 25286, Federal Center, Denver, CO 80225**

Residents of Alaska may order maps from

**U.S. Geological Survey, Earth Science Information Center  
101 Twelfth Ave. - Box 12  
Fairbanks, AK 99701**

### OVER THE COUNTER

#### Books and Maps

Books and maps of the U.S. Geological Survey are available over the counter at the following U.S. Geological Survey Earth Science Information Centers (ESIC), all of which are authorized agents of the Superintendent of Documents:

- **ANCHORAGE, Alaska**—Rm. 101, 4230 University Dr.
- **LAKEWOOD, Colorado**—Federal Center, Bldg. 810
- **MENLO PARK, California**—Bldg. 3, Rm. 3128, 345 Middlefield Rd.
- **RESTON, Virginia**—USGS National Center, Rm. 1C402, 12201 Sunrise Valley Dr.
- **SALT LAKE CITY, Utah**—Federal Bldg., Rm. 8105, 125 South State St.
- **SPOKANE, Washington**—U.S. Post Office Bldg., Rm. 135, West 904 Riverside Ave.
- **WASHINGTON, D.C.**—Main Interior Bldg., Rm. 2650, 18th and C Sts., NW.

#### Maps Only

Maps may be purchased over the counter at the following U.S. Geological Survey offices:

- **FAIRBANKS, Alaska**—New Federal Bldg., 101 Twelfth Ave.
- **ROLLA, Missouri**—1400 Independence Rd.
- **STENNIS SPACE CENTER, Mississippi**—Bldg. 3101

# Thermodynamic Properties of Minerals and Related Substances at 298.15 K and 1 Bar ( $10^5$ Pascals) Pressure and at Higher Temperatures

By Richard A. Robie and Bruce S. Hemingway

## TABLE

1. Atomic weights of the elements for 1985 .....	4
--	---

## SYMBOLS, CONSTANTS, AND CONVERSION FACTORS

T	Temperature in Kelvins.
$T_{\text{tm}}$	Temperature of transition in Kelvins.
K	Kelvin, the unit of temperature. It is the fraction 1/273.16 of the thermodynamic temperature of the triple point of water.
J	Joule, the unit of energy (or work). One joule = 1/4.1840 thermochemical calories or 10 cm <sup>3</sup> •bar.
mol	Mole, the amount of substance of a system that contains as many elementary entities as there are atoms in 0.012 kilograms of carbon 12. It is identical with the gfw (gram formula weight).
p	Pressure in bars. One bar = 10 <sup>5</sup> Pascals or 0.1 MPa. The standard atmosphere is equal to 101325 Pascals. The kilogram•cm <sup>-2</sup> is equal to 98065.5 Pascals.
°	Superscript indicates that the substance is in its standard state, 1 bar (10 <sup>5</sup> Pascals) for a condensed phase.
$H_T^\circ - H_{298}^\circ$	Enthalpy at temperature T relative to 298.15 K in J•mol <sup>-1</sup> , also called the heat content.
$(H_T^\circ - H_{298}^\circ)T^{-1}$	Enthalpy function in J•mol <sup>-1</sup> •K <sup>-1</sup> (See note below).
$S_T^\circ$	Entropy at temperature T, in J•mol <sup>-1</sup> •K <sup>-1</sup> .
$(G_T^\circ - H_{298}^\circ)T^{-1}$	Gibbs energy function in J•mol <sup>-1</sup> •K <sup>-1</sup> .
$C_p^\circ$	Heat capacity at constant pressure in J•mol <sup>-1</sup> •K <sup>-1</sup> .
$V_{298}^\circ$	Volume of 1 mol of a substance at 1 bar pressure and at 298.15 K, in cm <sup>3</sup> , or J•bar <sup>-1</sup> .
$\Delta_{\text{fus}}H^\circ$	Enthalpy of melting at 1 bar pressure in J•mol <sup>-1</sup> .
$\Delta_{\text{tm}}H^\circ$	Enthalpy of transition at 1 bar pressure in J•mol <sup>-1</sup> .
$\Delta_{\text{vap}}H^\circ$	Enthalpy of vaporization to the ideal gas at 1 bar pressure at the normal boiling point in J•mol <sup>-1</sup> .
$\Delta_fH^\circ$	Enthalpy of formation from the elements in their reference states in J•mol <sup>-1</sup> .
$\Delta_fG^\circ$	Gibbs energy of formation from the elements in their reference states in J•mol <sup>-1</sup> .
$K_f$	Equilibrium constant of formation.
R	Gas constant, 8.31451±0.00007 J•K <sup>-1</sup> •mol <sup>-1</sup> .
F	Faraday constant, 96,485.309±0.029 J•V <sup>-1</sup> •mol <sup>-1</sup> .
$N_A$	Avogadro constant, (6.0221367±0.0000036) × 10 <sup>23</sup> mol <sup>-1</sup> .
log	Common logarithm, base 10.
ln	Natural logarithm, base e = 2.71828...
atm	Standard atmosphere.
$m=1$	The standard state for an electrolyte in aqueous solution is the hypothetical ideal solution at unit activity and with the ions at infinite dilution.

---

When multiple units appear in the denominator of the symbol (for example, enthalpy function), the SI system does not recommend a particular order. For example, the units for entropy are given as J mol<sup>-1</sup> K<sup>-1</sup> in table 2.11 and as J K<sup>-1</sup> mol<sup>-1</sup> in table 3.5 of the Greenbook (278).

# Thermodynamic Properties of Minerals and Related Substances at 298.15 K and 1 Bar ( $10^5$ Pascals) Pressure and at Higher Temperatures

By Richard A. Robie and Bruce S. Hemingway

## ABSTRACT

Selected values for the entropy ( $S^\circ$ ), molar volume ( $V^\circ$ ), and for the enthalpy and Gibbs energy of formation ( $\Delta_f H^\circ$  and  $\Delta_f G^\circ$ ) are given for 50 reference elements, 55 sulfides, 93 oxides and hydroxides, 141 silicates, and 154 other minerals and related substances at 298.15 K. For those minerals for which high-temperature heat-capacity or heat-content data are also available ( $(H_T^\circ - H_{298}^\circ)T^{-1}$ ,  $S_T^\circ$ ,  $(G_T^\circ - H_{298}^\circ)T^{-1}$ ,  $C_p^\circ$ ,  $\Delta_f H_T^\circ$ ,  $\Delta_f G_T^\circ$  and  $\log K_{f,T}$  are tabulated at 100 K intervals for temperatures up to 1800 K.

## INTRODUCTION

In the 17 years since the predecessor to this bulletin was published, an enormous body of new thermochemical and equilibrium measurements for minerals has been published, personal computers have become almost universally available, and a number of "internally consistent thermodynamic property databases" (ICTDB) have been published (37, 67, 117, 149, 150, 159, 187, 188, 374). (In this section, references are indicated by numbers in parentheses.) This report is an updated revision and expansion of U.S. Geological Survey (USGS) Bulletin 1452 (361) and entirely supersedes it. As an example of growth of the thermodynamic properties of mineral database, USGS Bulletin 1452 contained data for 58 silicate minerals whereas in the current set of tables this number has been increased to 141.

The purpose of these tables is to present a critical summary of the available thermodynamic data for minerals and related substances in a convenient form for the use of earth scientists. To make the tables as useful as possible, we have tried (1) to include enough auxiliary data so that a single set of tables would suffice for most calculations, (2) to ensure internal consistency, and (3) to provide the means for rapid revision and expansion as new data become available.

The tables in this compilation are divided into three sections. In the first section, values are given for the entropy ( $S_{298}^\circ$ ), molar volume ( $V_{298}^\circ$ ), enthalpy of formation

( $\Delta_f H_{298}^\circ$ ), Gibbs energy of formation ( $\Delta_f G_{298}^\circ$ ), and the logarithm of the equilibrium constant of formation ( $\log K_{f,298}$ ) for the reference elements, minerals, and other substances of geological interest (properties at 298.15 K and 1 bar). In the second section, coefficients for the polynomial used to represent the heat capacity at high temperature are tabulated together with the temperature limits of applicability. In the third section, values are given for the thermodynamic properties at 100 K intervals for temperatures up to 1800 K. The data are arranged in order of their conventional mineralogical groups. Within each group (for example, the oxides) the listing is by alphabetical order of the chemical symbol of the principal cation.

The data have been taken from the original literature, recent critical evaluations, or have been evaluated by the present authors and estimated uncertainties have been assigned to the thermodynamic properties at 298.15 K. The primary sources of data are indicated numerically in the thermodynamic table of properties at 298.15 K, as "S" for the reference to the data for the entropy, "H/G" for the reference to the formation properties, and "C" to references to measured heat capacities above 298.15 K. The references are listed in complete form following the tables. The entropy and heat-capacity values tabulated are based almost exclusively on calorimetric measurements whereas the values for the enthalpy or Gibbs energy of formation were obtained from both equilibrium and calorimetric measurements. The values for the thermodynamic properties of the reference elements have been taken from the JANAF tables (67), the CODATA (85) recommended values, or in the case of calcium, from measurement at the USGS (360). For those silicate glasses for which  $S_T^\circ - S_0^\circ$  has been determined calorimetrically and for which the enthalpy of fusion of the crystalline equivalent could be evaluated, the residual entropy (that is,  $S_0^\circ$ ) of the glass has been evaluated and added to the calorimetric entropy to obtain the correct entropy for use in thermodynamic calculations. Glasses and other phases for which  $S_T^\circ - S_0^\circ$  has been measured but for which the residual entropy has not been evaluated are indicated by a "+" sign and the user must be aware that the

value tabulated does not include the configurational entropy.

Although a number of different forms of equations for the representation of the heat capacity at high temperatures have been proposed over the past 10 years, for example Berman (37), Fei and Saxena (104), Richet and Fiquet (342), we have retained the form adopted in the previous version of these tables,

$$C_p = A_1 + A_2 \cdot T + A_3 \cdot T^{-2} + A_4 \cdot T^{-0.5} + A_5 \cdot T^2$$

This equation can not be extrapolated beyond its upper limit. Inasmuch as most users will have access to a personal computer, the conversion from one form of equation to an alternative form is possible and is left up to the individual user's preference. The entropies listed in the table of coefficients for the  $C_p$  polynomials corresponds to the temperature at the lower limit of the temperature range for the polynomial. This is usually 298.15 K.

For several phases, the existence of multiple transitions at high temperature makes it impractical to provide a simple polynomial expression for the heat capacity. For such phases, for example Fe,  $\text{Cu}_{1.9}\text{S}$ , and several pyrrhotites, we have listed only the heat capacity at 298.15 K.

For these phases, one must go to the high-temperature table for the particular phase (if tabulated) to get the heat capacity (and entropy) above room temperature.

Internally consistent thermodynamic property data sets for silicate minerals have been published by Haas et al. (149), Holland and Powell (187, 188), Berman (37), Halbach and Chatterjee (150), and Saxena and Chatterjee (374) among others. Inasmuch as most of the authors relied on the same sources of calorimetric and equilibrium data to derive their adopted values, it is surprising that significant differences in their listed values for such important phases as grossular, anorthite, phlogopite and muscovite exist. For example, between the most frequently cited ICTDB, those of Berman (37) and Holland and Powell (188), the values of  $\Delta_r G_{298}^\circ$  calculated from their listed values of  $S_{298}^\circ$  and  $\Delta_r H_{298}^\circ$  differ by 5.7, 3.7 and 3.7  $\text{kJ}\cdot\text{mol}^{-1}$  for grossular, anorthite, and muscovite, respectively, and for analbite and muscovite the tabulated entropies differ by 4.4 and 9.1  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ , respectively. The point is, of course, that internal consistency does not imply that the derived values are accurate.

The reason for these discrepancies is most likely in the assumptions that the individual compiler makes concerning the state of internal Al/Si order. For a 1:3 Al/Si compound such as the alkali feldspars or micas the complete random mixing of the 3 Si and 1 Al over the 4 tetrahedral sites leads to a contribution to the entropy of 18.7  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ . However, if the aluminum-avoidance model is valid, the configurational entropy will be considerably smaller and of the order of 13 to 14  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ . The aluminum-avoidance model has not been calculated exactly and only approxi-

mate values are available. The values for the configurational entropies that have been derived from phase equilibrium studies by Holland and Powell (188) and by Berman (37) are 12.6 and 17.0  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$  for analbite and 16.0 and 15.1  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$  for sanidine, respectively. It appears that these calculated values for the entropy of disorder do not unequivocally support the aluminum-avoidance model but rather tend to yield a configurational entropy that is greater than that estimated by the aluminum-avoidance value, but definitely less than the fully random model. Any value of  $\Delta S$  greater than that calculated from aluminum-avoidance would presumably mean that this model was inapplicable at high temperatures; for example, at temperatures greater than 1300 K for analbite the disordering entropy would approach 18.7  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ . Moreover Goldsmith and Jenkins (123) have shown that the Al/Si disorder in  $\text{NaAlSi}_3\text{O}_8$  is a continuous function of the temperature and that it occurs over a range of several hundred degrees (500–1050 K) and occurs without change in symmetry.

As a consequence of these points the question arises whether one can extract meaningful (unique) values for the entropy of the disordered phase of an aluminosilicate from phase equilibrium studies without having additional information on the Al/Si distribution. For this reason, we have adopted the fully random model for tabulating the high-temperature properties for the Al/Si disordered feldspars and micas. For an extended discussion of the contribution to the entropy of silicate minerals arising from Al/Si or magnetic spin disorder, see Ulbrich and Waldbaum (413).

The differences in the derived values for the thermodynamic properties of phases in the CASH system is due in part to the existence of two calorimetric values for the entropy of grossular which differ from one another by 4.6  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ . The value of Westrum et al. (438) was determined on a natural sample and involved a substantial correction for impurities. The value given by Haselton and Westrum (157) was derived from measurements on a synthetic sample. The heat capacity of the synthetic sample used by Haselton and Westrum (157) was later remeasured at the USGS by the present authors (359), who found an entropy  $S^\circ(\text{Ca}_3\text{Al}_2\text{Si}_3\text{O}_{12}, 298.15 \text{ K})$  of 259.9  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$  which agrees with the Haselton and Westrum value to within 0.2  $\text{J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$  (0.08 percent). For this reason we have accepted the Haselton-Westrum value for the entropy of grossular in evaluating the thermodynamic properties of phases in the CASH system.

## PHYSICAL CONSTANTS AND ATOMIC WEIGHTS

The symbols and constants used to prepare these tables are listed in the table of contents. The units adopted for reporting the thermodynamic properties are those of the International System of Units (SI). A formal description of

the SI system is given by Goldman and Bell (122). The recommended symbols and terminology used are those from the International Union of Pure and Applied Chemistry (IUPAC), "Quantities, Units and Symbols in Physical Chemistry", by Mills et al. (278) and commonly called the "Greenbook". The Greenbook is also a convenient source for the CODATA values of the fundamental physical constants, the 1985 atomic weights of the elements, and contains a detailed description of the SI system of units.

Values for the gas constant ( $R$ ), the Faraday constant ( $F$ ), and the Avogadro constant ( $A$ ) used in the calculations are those adopted by the CODATA Task Group from the least squares evaluation of Cohen and Taylor (75). For convenience, we also give values for the atomic weights for 1985 (scale  $C^{12} = 12.000$ , Mills et al. (278)) in alphabetical order by their chemical symbol in table 1.

## REFERENCE STATES

The reference pressure for the standard state adopted for these tables is 1 bar, that is  $10^5$  Pascals. For a gaseous phase,  $C_p^\circ$ ,  $(H_T^\circ - H_{298}^\circ)T^{-1}$ , and  $\Delta_f H^\circ$  are independent of pressure, but the numerical values of  $S^\circ$ ,  $(G_T^\circ - H_{298}^\circ)T^{-1}$ ,  $\Delta_f G^\circ$  depend upon the choice of pressure. The change in pressure from  $p = 1$  atm (1.0135 bar) to 1 bar yields  $\Delta S = 0.11 \text{ J}\cdot\text{mol}^{-1}\cdot\text{K}^{-1}$ . For a condensed phase (liquid or solid), it can be shown that the effect of changing the reference pressure from 1 atm to 1 bar has only a trivial effect upon all the thermodynamic properties tabulated in this report except for  $\Delta_f G^\circ$ , where a change will occur if one of the reference elements (usually oxygen) is a gas.

The standard states for the condensed elements are the most stable form at 1 bar pressure and the stated temperature. For gaseous elements, the standard state is the ideal gas at 1 bar pressure. Data are listed for the elements in their standard reference states, and for a few in nonstandard states; for example,  $S^2$  gas and the diamond form of carbon. The reference state adopted for an element above its normal boiling or sublimation temperature is not necessarily its equilibrium state. Thus, at equilibrium, liquid sulfur boils at 1 bar pressure and approximately 716.9 K to a gas composed of  $S$ ,  $S_2$ ,  $S_4$ ,  $S_6$ ,  $S_8$ , etc., but for our reference table, we have assumed the gas phase to be only  $S_2$ . For the reference state table for sulfur we have followed the JANAF (67) tables procedure using 882.12 K as the fictive boiling temperature at which liquid sulfur is in equilibrium with  $S_2$  gas at 1 bar pressure. Because of the convenience of using diatomic sulfur gas in calculations of sulfide mineral equilibria we have included a second set of high-temperature tables for which the reference state for calculating  $\Delta_f G^\circ$ , and  $\Delta_f H^\circ$  and  $\log K_f$  for the sulfide phase is  $S_2$  gas. The user is cautioned not to intermix values from the two different reference states in their calculations. In other ambiguous cases, we have chosen either the dominant species in the gas

or that species for which the best thermodynamic data are available as the reference state.

The reference states for  $\Delta_f H^\circ$ ,  $\Delta_f G^\circ$ , and  $\log K_f$  of the compounds are the elements in their standard states at 1 bar pressure and the stated temperature.

## METHODS OF CALCULATION

Having chosen what we believe are the currently "best available" values for  $H_T^\circ - H_{298}^\circ$ , or  $C_p^\circ(T)$ ,  $S_{298}^\circ$  and either  $\Delta_f H_{298}^\circ$  or  $\Delta_f G_{298}^\circ$ , we have calculated the Gibbs energy function, and the enthalpy, Gibbs energy, and the equilibrium constant of formation at 100 K intervals using the following relations:

$$(G_T^\circ - H_{298}^\circ)T^{-1} = (H_T^\circ - H_{298}^\circ)T^{-1} - S_T^\circ$$

$$\Delta_f H_T^\circ = \Delta_f H_{298}^\circ + \Delta(H_T^\circ - H_{298}^\circ)$$

$$\Delta_f G_T^\circ = \Delta_f H_{298}^\circ + T\Delta[(G_T^\circ - H_{298}^\circ)T^{-1}]$$

and

$$\log K_{f,T} = \Delta_f G_T^\circ / (2.30258 RT) = -\Delta_f G_{298}^\circ / (19.145T) - 1$$

These values together with  $C_p^\circ$ ,  $S_T^\circ$  and  $(H_T^\circ - H_{298}^\circ)T^{-1}$  are tabulated in the third section.

Transitions in heat capacity are treated in the standard manner: heat capacity curves are fit to the experimental values above and below the transition; values calculated from an extrapolation of the equation to the transition temperature are compared to the experimental values; and differences are summed to give an enthalpy of transition that is applied at the transition temperature.

The uncertainties assigned to the properties apply only to the values at 298.15 K. The principal source has been the original report of the experimental data. By convention, the uncertainty interval reported for calorimetric measurements is twice the standard deviation of the mean; that is,

$$\delta = 2[\sum (x_i - x_m)^2 / n(n-1)]^{1/2}$$

where  $x_i$  is the value for an individual measurement,  $x_m$  is the arithmetic mean of all the measurements, and  $n$  is the number of measurements.

For generating the high-temperature tables, the input data supplied to the computer are the identifying name of the substance, the entropy, the enthalpy of formation at 298.15 K, the number of atoms of each element in the chemical formula, and the coefficients for the heat capacity equation. A commercial spreadsheet is used to compute the formula weight of the compound and values for  $S_T^\circ$ ,  $\Delta_f H_T^\circ$ ,  $\Delta_f G_T^\circ$ ,  $\log K_{f,T}$ ,  $C_p^\circ$ ,  $(H_T^\circ - H_{298}^\circ)T^{-1}$ , and  $(G_T^\circ - H_{298}^\circ)T^{-1}$ , at 100 K intervals up to 1800 K. Auxiliary data such as the melting and boiling points and enthalpies of melting and vaporization are also included. In addition, coefficients

from a regression performed on the calculated values of  $\Delta_f G_T^\circ$  are included. The equation adopted is:

$$\Delta_f G_T^\circ = A + BT + CT^{-2}$$

The coefficients for the equations are listed, in scientific notation, at the bottom of the page for the individual high-temperature tables. The equations are given only for those minerals for which the regression yielded a fit of better than 1 percent.

## ADDITIONAL COMMENTS

Small numbers of some groups are presented with other groups for convenience and economy. Examples

include tellurides, selenides and arsenides that are included with sulfides and sulfosalts, and methane, cohenite, and ammonia that are included with the elements.

The data available in this publication are also available on diskette for a nominal fee through the Generic Mineral Technology Center for Pyrometallurgy at the University of Missouri at Rolla as a part of the FREED database. FREED is a thermodynamic database program for storing, retrieving, editing, and manipulating thermodynamic data on a computer. FREED was developed with support from the U.S. Department of Interior's Mineral Institute Program, administered by the U.S. Bureau of Mines, and the U.S. Department of Energy through the Westinghouse Savannah River Plant.

449. Zhogin, D. Yu., Kosarukina, E. A., and Kolesov, V. P., 1980, Heat capacity in the 10-300 K range and thermodynamic functions of tetragonal tin dioxide: *Zhur. Fiz. Khimii*, v. 54(4), p. 916-920.
450. Heat capacity of hercynite estimated as  $C_p(\text{FeAl}_2\text{O}_4) = \sum C_p(\text{FeO}) + C_p(\text{Al}_2\text{O}_3)$  by Robie. Entropy of  $\text{MnSO}_4$  and other values estimated by Robie.
451. Enthalpies of solution of members of the nepheline-kalsilite series were reported by Hovis and Roux (Hovis, G.L. and Roux, J., 1993, Thermodynamic mixing properties of nepheline-kalsilite crystalline solutions: *Am. Jour. Sci.*, v. 293, p. 1108-1127.). Using enthalpy of solution values calculated from their equations 4 and 5, ancillary data from (166, tables 1-4), and unpublished enthalpy of solution data for KCl from Hemingway ( $\Delta H(\text{soln}) = 6.045 - 0.0189t(^{\circ}\text{C})$ ), we calculate  $\Delta_f H = -2090.4 \pm 2.5$  and  $-2124.7 \pm 2.5 \text{ kJ} \cdot \text{mol}^{-1}$ , respectively, for nepheline and kalsilite. These results are in good agreement with values given in (361) of  $-2092.1 \pm 2.4$  and  $-2121.9 \pm 1.4 \text{ kJ} \cdot \text{mol}^{-1}$ , respectively, but based on less pure samples (20, 171). These results are significantly less negative than the formation properties calculated by (188) from a limited number of phase equilibrium experiments. The calorimetrically determined value of  $-3037.8 \pm 2.8 \text{ kJ} \cdot \text{mol}^{-1}$  for leucite (171, 20) is preferred to that derived by (188) from a limited number of phase equilibrium data ( $-3020.0 \pm 2.7 \text{ kJ} \cdot \text{mol}^{-1}$ ).

452. Heat capacity measurements on a synthetic alunite are combined with earlier results by Kelley et al. (219) to estimate the entropy at 298.15 K. The reaction scheme used by Kelley et al. (219) is recalculated using modern values for the enthalpy of formation of the reference phases. See, Hemingway, B.S. and Robie, R.A., 1994, Heat capacity and enthalpy of formation of synthetic alunite: U.S. Geological Survey Open-file Report 94-688, 8 p.
453. High temperature heat capacities are derived from 244, 299, 402.
454. The Gibbs energy of livingstonite at 298.15 K is estimated from the study of (Sorokin, V.I., Dadze, T.P., and Pokronskiy, V.A., 1988, The Gibbs free energy of formation of livingstonite: *Geokhimiya*, No. 6, 897-900).
