Return to Normal Streamflows and Water Levels: Summary of Hydrologic Conditions in Georgia, 2013

The U.S. Geological Survey (USGS) South Atlantic Water Science Center (SAWSC) Georgia office, in cooperation with local, State, and other Federal agencies, maintains a long-term hydrologic monitoring network of more than 340 real-time continuous-record streamflow-gaging stations (streamgages), including 10 real-time lake-level monitoring stations, 67 real-time surface-water-quality monitors, and several water-quality sampling programs. Additionally, the SAWSC Georgia office operates more than 180 groundwater monitoring wells, 39 of which are real-time. The wide-ranging coverage of streamflow, reservoir, and groundwater monitoring sites allows for a comprehensive view of hydrologic conditions across the State. One of the many benefits of this monitoring network is that the analyses of the data provide a spatially distributed overview of the hydrologic conditions of creeks, rivers, reservoirs, and aquifers in Georgia.

Streamflow and groundwater data are verified throughout the year by USGS hydrographers. Hydrologic conditions are determined by comparing the results of statistical analyses of the data collected during the current water year (WY) to historical data collected over the period of record. Changing hydrologic conditions emphasize the need for accurate, timely data to help Federal, State, and local officials make informed decisions regarding the management and conservation of Georgia’s water resources for agricultural, recreational, ecological, and water-supply needs and for use in protecting life and property.

Drought conditions, persistent in the area since 2010, continued into the 2013 WY. In February 2013, Georgia was free of extreme (D3) drought conditions, as defined by the U.S. Drought Monitor, for the first time since August 2010 due to extended periods of heavy rainfall (U.S. Drought Monitor, 2013). According to the Office of the State Climatologist, the city of Savannah recorded 9.75 inches of rain in February 2013, the highest monthly total in February out of 143 years of record. Macon and Columbus also received record rainfalls in February 2013. Above-normal precipitation continued in June 2013, and the cities of Augusta and Savannah recorded the wettest June on record. In July, precipitation for the entire State of Georgia was 3.53 inches above normal (Dunkley, 2013). Above-normal rainfall from February to September 2013 increased streamflow and raised groundwater levels, and lakes and reservoirs were raised to full-pool elevations.

Water Resources Internet Tools

Historically, hydrologic data collected by the USGS were compiled into annual data reports; however, this method of publication has been discontinued. Current and historical data are now available through the National Water Information System Web interface, or NWISWeb, at http://waterdata.usgs.gov/nwis/ (U.S. Geological Survey, 2013a).

The USGS has several water resources Internet tools designed to provide users with current streamflow and groundwater data, flood inundation maps, stream statistics, and water-quality information (U.S. Geological Survey, 2013b). Two of these Internet tools are WaterNow and WaterAlert. WaterNow, available at http://water.usgs.gov/waternow/, allows users to request current data for a USGS site by using a mobile phone through text messaging or an email. WaterAlert, available at http://water.usgs.gov/wateralert/, will notify a user by text message or email when a user-defined threshold is exceeded at a real-time USGS site.

(From U.S. Geological Survey, 2013b)
Daily Discharge and 7-Day Average Streamflow Conditions, 2013 Water Year

**Chattooga River at Summerville, Ga. 02398000**

The Chattooga River flows from the northwestern corner of Georgia, in the Blue Ridge Physiographic Province, into Alabama where it flows into Weiss Lake (U.S. Geological Survey, 1976). For the majority of the 2013 WY, 7-day average streamflow conditions were "normal" to "much above normal." Daily discharge for most of the 2013 WY was in the "maximum" range. New record high daily discharges were observed in January, April, May, June, and July.

**Ocmulgee River at Macon, Ga. 02213000**

The Ocmulgee River flows out of Jackson Lake and joins the Oconee River to form the Altamaha River in the Coastal Plain Physiographic Province in central Georgia (U.S. Geological Survey, 1976). At the start of the 2013 WY, streamflows were approaching a new record low. Starting in December 2012, daily discharge increased and fluctuated between the “median” and “maximum” ranges of historical daily mean flow. In February 2013, the 7-day average discharge was mostly “normal,” with several days also having “much above normal” flows.

**Sweetwater Creek near Austell, Ga. 02337000**

Sweetwater Creek is a major tributary of the Chattahoochee River in the Piedmont Physiographic Province (U.S. Geological Survey, 1975). For the first half of the 2013 WY, 7-day average streamflow conditions were “below normal” to “much below normal,” and record low 7-day average streamflows were observed in November and December. Steady precipitation in the area, starting in December, brought in much needed rainfall, and the 7-day average streamflows fluctuated mostly between “normal” and “much above normal” for the rest of the 2013 WY. New minimum daily mean discharges were observed in October, November, and December, followed by streamflows in the “median” and “maximum” ranges for the remainder of the 2013 WY.

**Withlacoochee River at US 84 near Quitman, Ga. 02318500**

The Withlacoochee River flows in the Suwannee River Basin in the southern coastal plain of Georgia (U.S. Geological Survey, 1976). For much of the 2013 WY, 7-day average streamflow conditions were “normal,” “much above normal,” and record-high 7-day average streamflows were observed during March, July, and August. Daily discharge was mostly in the “maximum” range from February to September. New maximum daily-mean discharges were recorded during February, March, July, and August.
Climate Response Network

The USGS maintains a network of groundwater wells to monitor the effects of droughts and other climate variability on groundwater levels. These levels are part of the Climate Response Network, which is designed to measure the effects of climate on groundwater levels in unconfined aquifers or near-surface confined aquifers where pumping or other human influences on groundwater levels are minimal (U.S. Geological Survey, 2007, 2013d). The national network consists of about 130 wells, of which 15 are located in Georgia. These wells are monitored as part of the USGS Groundwater Resources and Cooperative Water Programs. Current conditions of groundwater wells in the Climate Response Network can be accessed online at [http://groundwaterwatch.usgs.gov](http://groundwaterwatch.usgs.gov/). The hydrographs presented in figure 4 are for selected wells in Georgia having at least 5 years of continuous data.

Aquifers in Georgia

[Map of Georgia showing aquifers and surface water features]

Well 07H003 is in Miller County in southwestern Georgia and is completed in the surficial aquifer, which is an unconfined aquifer in this area (Peck and others, 2013). Water levels in this well generally rose rapidly during wet periods and declined slowly during dry periods. The water level in well 07H003 responds to seasonal change similar to streamflow at the nearby streamgage on Spring Creek near Iron City, Ga. (02357000), which indicates atmospheric, surface-water, and groundwater interactions. The water level in well 07H003 was below the historical daily median at the start of the 2013 WY until February. In February, the area received more than 10 inches of precipitation for the month, and the water level rose nearly 6 feet below land surface and was above the historical daily median. The water level slowly declined below the historical daily median from March through June. New maximum daily mean water levels were recorded during the months of July and August after the area received more than 13 and 9 inches of precipitation, respectively, during these months.

Well 16MM03 is in White County in northeastern Georgia and is completed in the crystaline-rock aquifer. Water is stored in the regolith and fractures, and the water level is affected by precipitation and evapotranspiration (Cressler and others, 1983). Precipitation can cause a rapid water-level rise in wells tapping aquifers over thin regolith (Peck and others, 2013). The water level in well 16MM03 responds to seasonal change similarly to streamflow at the nearby streamgage on the Chattahoochee River at Helen, Ga. (02300450), which indicates atmospheric, surface-water, and groundwater interactions. As the drought continued into the 2013 WY, new minimum daily mean water levels, approximately 5.5 feet below land surface, were recorded at the end of November and beginning of December. In December and January, the area received more than 7 inches of precipitation, respectively, and the water level in well 16MM03 slowly declined below the historical daily median from May through the remainder of the water year. In July, August, and September, new maximum daily mean water levels were recorded after the area received more than 8 inches of precipitation in July and nearly 7 inches in August.

Well 10G313 is in Laurens County in east-central Georgia and is completed in the semiconfined part of the Upper Floridan aquifer, which is an unconfined aquifer in this area. Water levels in semiconfined areas of the Upper Floridan aquifer fluctuate seasonally in response to variations in precipitation, evapotranspiration, and natural drainage or discharge (Peck and others, 2013). The water level in well 10G313 responds to seasonal change similarly to streamflow at the nearby streamgage on the Canoochee River at Bridge 38, at Fort Stewart, Ga. (022203518), which indicates atmospheric, surface-water, and groundwater interactions. The water level in well 10G313 was approximately 1 to 2 feet below the historical daily median at the start of the 2013 WY. In February, the area received more than 10 inches of precipitation for the month, and the water levels rose nearly 6 feet, remaining above the historical daily median through the end of the WY.
Discrete and Continuous Water-Quality Conditions in Georgia

Water-quality and quality information are both important for ensuring adequate water availability for human consumption, industrial uses, and aquatic ecosystems. Water-quality conditions are related strongly to water quantity. Precipitation and streamflow conditions are primary agents of delivery and transport of both point- and nonpoint-source contaminants (Hirsch and others, 2006).

Georgia Environmental Protection Division

The USGS provides the Georgia Department of Natural Resources Environmental Protection Division (GaEPD) and the public with a relevant, nationally consistent database of long-term water-quality data, which assists the GaEPD in meeting its responsibilities under the Clean Water Act. The USGS-GaEPD discrete water-quality sampling program is designed to collect data systematically, regardless of hydrologic conditions. Water-quality data for Georgia streams are available to the public at http://waterdata.usgs.gov/ga/nwis/qw/. In addition, the USGS-GaEPD program collects continuous water-quality data at three Georgia Environmental Protection Division (GaEPD) program collects continuous water-quality data at three sites, including the Chattahoochee River near Fairburn, Ga.

Chattahoochee River near Fairburn, Ga. 02337170

The Chattahoochee River near Fairburn, Ga., station (02337170), located just south of Atlanta in the Metro North Georgia Water Planning District planning region, has a drainage area of 2,880 square miles. Water use for this stream reach is classified as “fishing” under Georgia Code 1991-3-6.03, which requires the daily mean dissolved oxygen concentration in the stream be equal to or greater than 5.0 milligrams per liter (Georgia Department of Natural Resources, 2013). No daily mean dissolved oxygen level fell below the “fishing” criteria at station 02337170 during the 2013 WY (graph below).

Urban Water-Quality Program

Numerous real-time water-quality monitors are co-located at streamflow stations around the Atlanta metropolitan area. Gwinnett County determines water-quality trends. Data like these are summarized in scientific investigations such as Watershed Characteristics and Water-Quality Trends and Loads in 12 Watersheds in Gwinnett County, Georgia (Joiner and others, 2014). Urban water-quality conditions are primary agents of delivery and transport of both point- and nonpoint-source contaminants (Hirsch and others, 2006). Relating streamflow to continuous water-quality data and discrete water-quality measurements collected at this station during the 2013 WY. Specific conductance and turbidity react similarly during changing streamflow conditions. Chronic levels of suspended materials in streams are often the cause of stream impairment (U.S. Environmental Protection Agency, 2012). TSS concentrations and turbidity levels were typically greater during stormflow samples compared to base-flow samples because these constituents are washed from the land and impervious surfaces into streams during periods of rainfall runoff and suspended in the water column, demonstrating a relation between water quality and water quantity (graphs below).

Real-time continuous specific-conductance measurements were collected at this station during the 2013 WY. Specific conductance is a measure of dissolved ionic constituents, such as salts, in water. Specific conductance and total dissolved solids were typically lower in samples collected during stormflow because dissolved constituents in streams can be diluted during rainfall runoff, as compared to lower flows. At times, however, some dissolved constituents are transported during higher discharges.

Yellow River at GA 124 near Lithonia, Ga. 0207120

Yellow river station 0207120, located in Gwinnett County, Ga., in the Altamaha River Basin, has a drainage area of 162 square miles. During the 2013 WY, real-time continuous turbidity was measured, and 10 total suspended solids (TSS) samples were collected, 7 during stormflow and 3 during base flow. Turbidity is a measure of water clarity and light reflected off particles in streamflow caused by clay, silt, and fine suspended inorganic and organic matter; therefore, TSS and turbidity react similarly during changing streamflow conditions. Chronic levels of suspended materials in streams are often the cause of stream impairment (U.S. Environmental Protection Agency, 2012). TSS concentrations and turbidity levels were primarily greater during stormflow samples compared to base-flow samples because these constituents are washed from the land and impervious surfaces into streams during periods of rainfall runoff and suspended in the water column, demonstrating a relation between water quality and water quantity (graphs below).
Major lakes and reservoirs throughout Georgia are managed primarily by the U.S. Army Corps of Engineers and Georgia Power Company to provide water for public and industrial use, flood protection, power generation, wildlife management, and recreation. To manage lakes and reservoirs, tools such as computer models that rely on real-time USGS streamflow data help to predict changes in climatic conditions and water demands.

Lake Sidney Lanier on the Chattahoochee River is the primary drinking-water source for much of Metropolitan Atlanta. Lake Sidney Lanier is the farthest upstream reservoir in a series of reservoirs that include West Point Lake, Walter F. George Lake, and Lake Seminole. On December 23, 2012, Lake Sidney Lanier reached the 2013 WY minimum elevation of 1,056.33 feet. From January to April 2013, the inflow was 3.6 times greater than the outflow, and the lake level increased nearly 16 feet to a full-pool elevation of 1,072.24 feet, and remained near full pool for the remainder of the 2013 WY.

West Point Dam provides flood protection and hydroelectric power to Troup County. The water-level elevation of West Point Lake at the start of the 2013 WY was approximately 10 feet below full pool. From December 2012 to January 2013, the water level was raised 13 feet to maintain a level near the top of conservation pool for the remainder of the water year.

Allatoona Lake is on the Etowah River and is managed by the U.S. Army Corps of Engineers. During the 2013 WY, the water level of Allatoona Lake remained above or just below the top of conservation pool.

Hartwell Lake is the most upstream major reservoir on the Savannah River in a series of reservoirs that include Richard B. Russell and J. Strom Thurmond Lakes. These three lakes on the Savannah River are managed by the U.S. Army Corps of Engineers for water supply, power generation, and water-quality needs of the Savannah River from below Thurmond Dam to Savannah, Georgia, and the Atlantic Ocean (U.S. Army Corps of Engineers, 2013a). During the 2013 WY, Hartwell Lake reached a minimum elevation of 644.77 feet on December 15, 2012. Between January and April 2013, the inflow was 2 times greater than outflow, and the lake level increased more than 20 feet to a full-pool elevation of 664.79 feet. The water-level elevation remained near full pool for the remainder of the 2013 WY.
