Maryland, called “America in Miniature,” encompasses nearly every geographical feature in the United States except a desert. Water dominates the State, whose borders run along much of Chesapeake Bay. The bay is the country’s largest estuary, where freshwater from watershed tributaries mingles with the ocean’s saltwater and teems with life.

The Chesapeake Bay faces threats from erosion, pollution, rising sea levels, and natural disasters. Because the Chesapeake Bay is prominent in Maryland’s history, economy, natural diversity, and way of life, protecting its waters and ecosystems is a priority for the State. Landsat imagery helps with a number of these efforts. Maryland also has a special relation with Landsat satellites; the USGS manages their flight operations out of NASA’s Goddard Space Flight Center in Greenbelt.

Here are several ways Landsat data have been benefiting Maryland.

**Lowering Pollutants Entering Chesapeake Bay**

Land cover data provided by Landsat satellites are helping Maryland and other States whose water drains into the Chesapeake Bay watershed to set their specific total maximum daily loads (TMDLs) of pollutants. TMDLs are estimates of the amount of certain pollutants that a body of water could handle before its quality is adversely affected. TMDLs can include excess nutrients, sediments, and contaminants. Landsat data help identify areas for targeting nonpoint source pollution, looking in part at the type of surface that the runoff travels over, such as pavement or cropland or forest (USGS, 2017).

This image of the Chesapeake Bay, America’s largest estuary, was created using Provisional Surface Reflectance data from five Landsat 8 scenes acquired in October and November 2014.

**National Land Imaging Program Benefits—Maryland**

The U.S. Geological Survey (USGS) National Land Imaging Program provides a wide range of satellite imagery and other remotely sensed and geospatial data to Government, commercial, academic, and public users. Those users can get worldwide access to Landsat satellite data through the National Land Imaging Program-funded USGS Earth Resources Observation and Science Center.
Helping Farmers Reduce Runoff

Images from Landsats 5 and 8 were used recently to help create a tool for the Maryland Department of Agriculture (MDA) to monitor and analyze the effectiveness of winter cover crops. The MDA provides a subsidy to encourage farmers to plant winter cover crops that help prevent erosion and runoff. The new tool allows the MDA to check the effectiveness of the cover crops, without requiring a site visit, and can help identify ways to improve the use of cover crops (Voiland, 2017).

The Operational Land Imager on Landsat 8 captured a natural-color image on January 5, 2015, that shows winter cover crops being grown on farmland along Tuckahoe Creek and the Choptank River on the Delmarva Peninsula.

Assessing Coastal Wetlands

Landsat images are being used by the USGS to help assess the status of coastal wetlands. Long-term climate change-related processes, such as rising sea levels, can change wetlands, but so can sudden storms. For example, Assateague Island, a barrier island famed for its wild horses off the coast of Maryland, had significant erosion, saltwater overwash, and deposition from Hurricane Sandy. The use of Landsat data to understand the connections among ocean coastlines and the shorelines of estuaries and barrier islands, including interior wetlands, can help coastal land managers make decisions and predictions about the effects of future events (Douglas and others, 2018).

Mapping High-Tide Flooding

Rising sea levels have increased the frequency of flooding caused by higher-than-historically normal tide levels along Maryland’s shoreline. The Landsat 7 and 8 satellites have helped with mapping of flooding caused by these high tides. In Annapolis, one site prone to such floods, water can fill streets and parking lots and even affect the U.S. Naval Academy. Compounding factors for these high tides include moon phases, wind direction, and land subsidence (Marder, 2020).

The U.S. Naval Academy is located along the Chesapeake Bay in Annapolis, Maryland. The campus has taken measures to minimize flooding damages, but in high-tide flooding, Ramsay Road routinely floods. Photograph credit: U.S. Naval Park Service.
