ATLAS HA-453 (SHEET 1 OF 3)

WITHDRAWAL USE OF WATER IN 1968
IN MILLION GALLONS PER DAY

The Piedmont-Savannah River basin has a topographic shaped largely by the bedrock surface. Two distinct topographic patterns are evident in the study area. The eastern one-fifth is characterized by rolling hills and wide, level valley floors. Continental glacial erosioned the bedrock surface and deposited large quantities of unconsolidated rock material. The western four-fifths is characterized by rugged, steep-walled valleys and high relief. Glacial deposits are absent, and streams have cut deeply into the relatively hard bedrock.

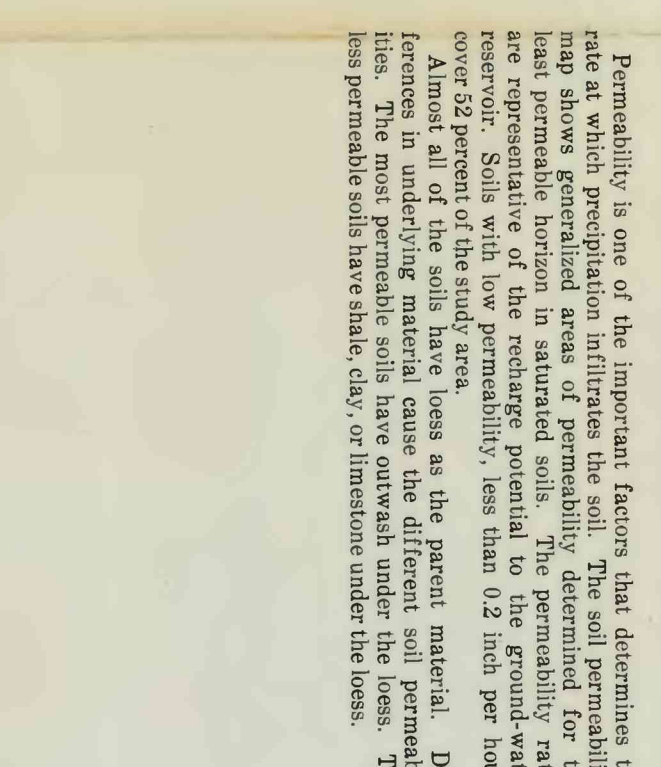

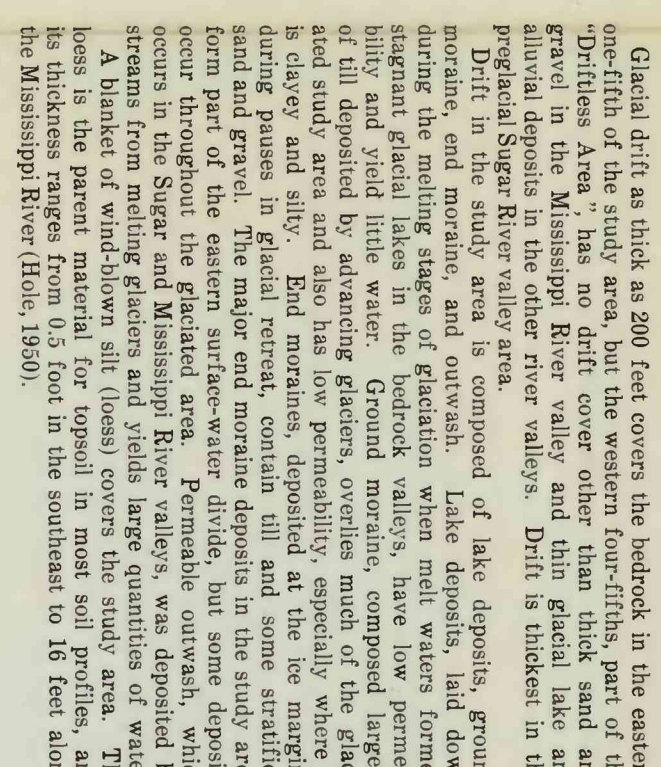

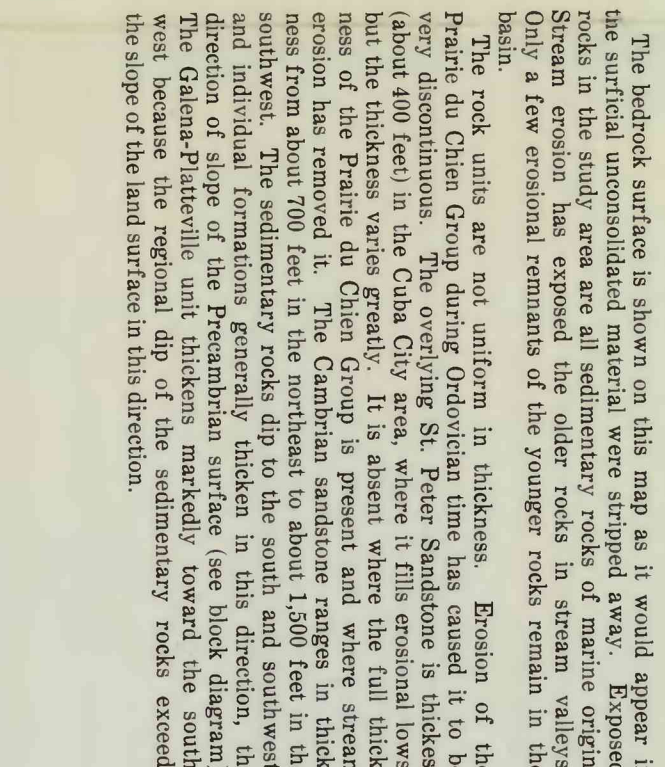

Fluvial processes, such as erosion, incision, sequence, and lateral accretion of the river, have shaped the bedrock surface. The diagram represents a rock unit shown on the faces of the diagram are representative of the rest of the area. Cambrian sandstones underlie the entire basin. Younger formations are discontiguous because erosion

Younger formations are discontinuous because erosion has removed them in some places (Fig. 1).

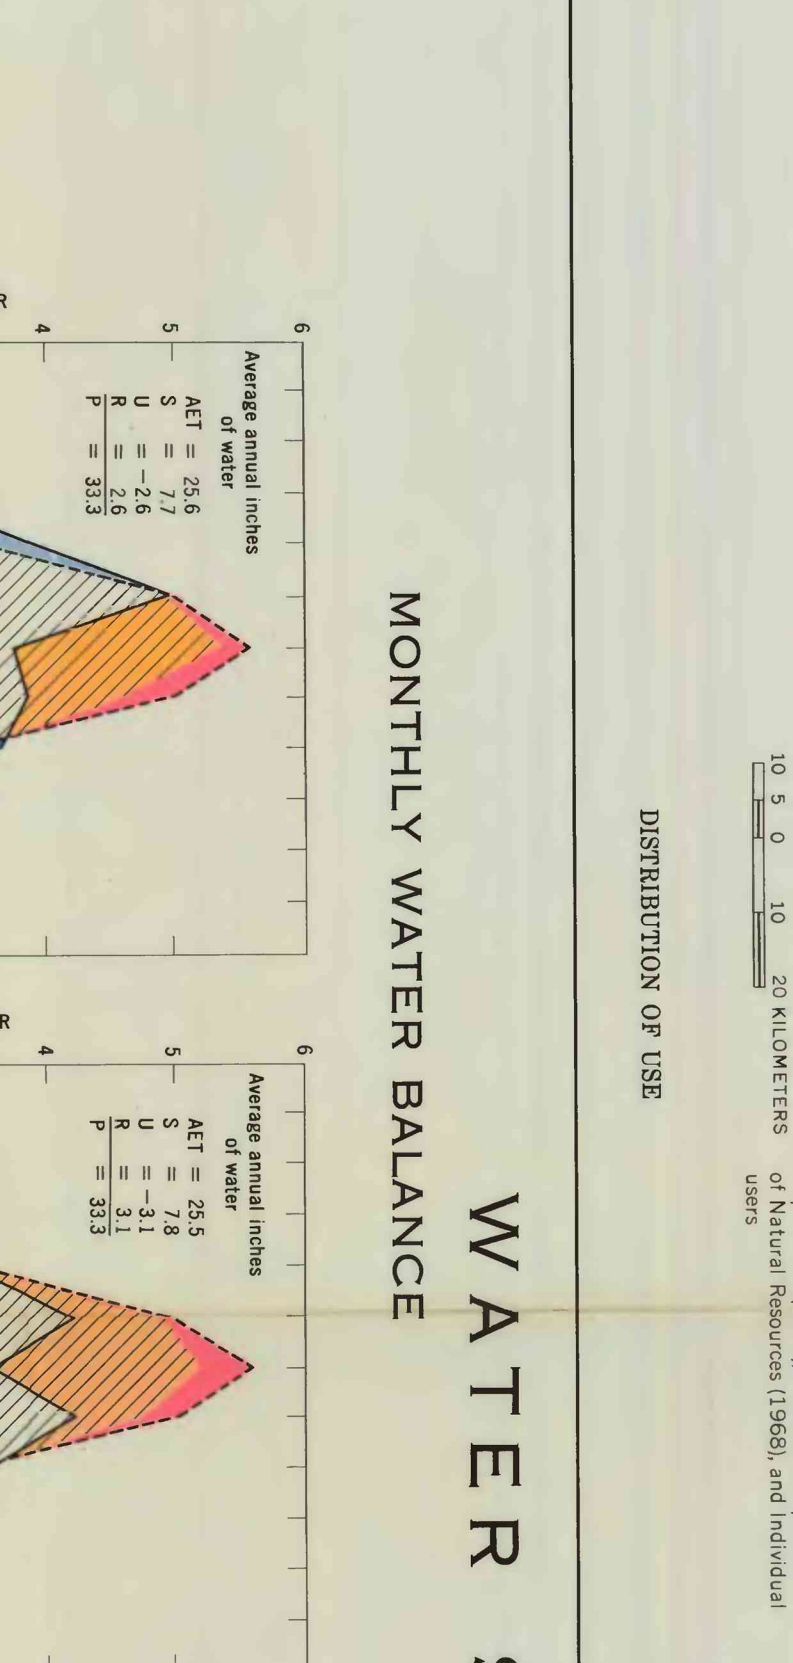

CS8

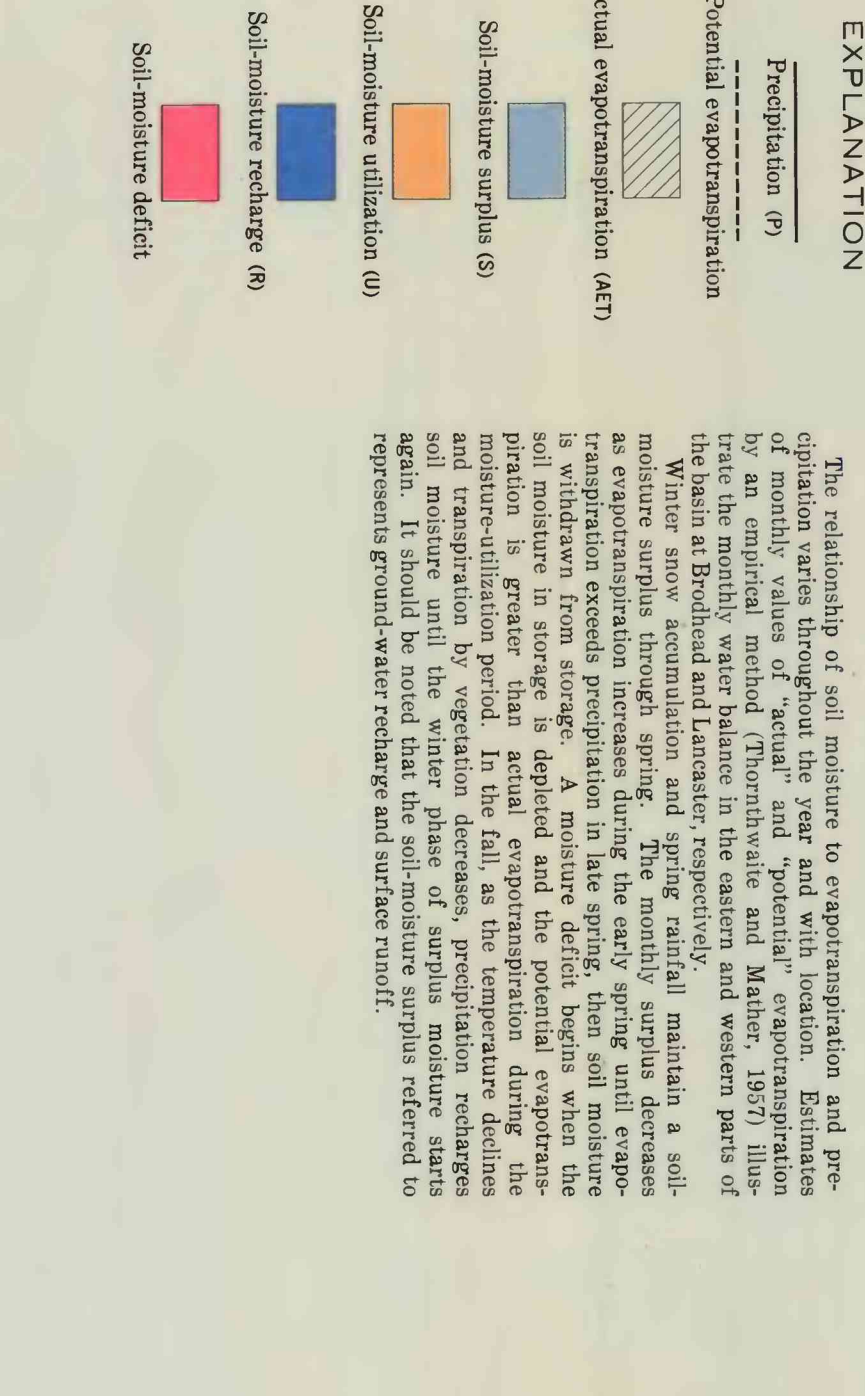

TOPOGRAPHY AND DRAINAGE

Geologic structure completely controls the drainage pattern in the "Driftless Area" (Fairbridge, 1963). The location and trends of the major drainage basins, and the location of the headwaters of the tributaries, are influenced by the trends of the structural ridges within a framework of the regional dip that controls the gross drainage trends. The fine details of the drainage pattern are influenced by local topographic features, local structural patterns and different trends of valley segments, low-order streams, and the shape of valley beds. The interaction between these elements is complex, and the influence of one structural element may mask the effects of the other.

[illegible]

ther mix obtain their water from a combination of the Galesville and sandstone aquifers.

Evapotranspiration, the return of water to the atmosphere by evaporation and plant transpiration, is composed here as the difference between precipitation and the sum of runoff, infiltration, and storage. Runoff is the portion of precipitation that is not accounted for by less than 1 inch of the total average annual evapotranspiration. Much consumptive use of water has been included in evapotranspiration but it less than 1 percent of the total.
