GEOLOGIC MAP OF THE ROAN PLATEAU AREA, NORTHWESTERN COLORADO

By
William J. Hall, Jr., Robert B. O'Sullivan and Marjorie C. Smith
1989

CORRELATION OF MAP UNITS

DESCRIPTION OF MAP UNITS

- Qal** Alluvium (Holocene)—Mud, silt, sand, and gravel. Mostly locally derived unconsolidated stream deposits on floors of larger valleys. Includes fan deposits at mouths of minor tributaries. Deposits of colluvial fans are dominant type of alluvium along several larger valleys. Also includes some slope wash along steep valley walls.
- Qts** Talus and sheetwash deposits (Holocene)—Unconsolidated poorly sorted rubble of mud, silt, sand, and gravel on or at the base of steep canyon walls. Only the thickest or most extensive deposits are shown.
- Qtp** Landslide deposits (Holocene and Pleistocene)—Slide masses and slumped ground. Most common on lower slopes and at bases of steep canyon walls. Most originate in outcrops of the Douglas Creek, Garden Gulch, and Anvil Points Members of the Green River Formation, and the Wasatch Formation.
- Tug** Terrace and pediment deposits (Holocene and Pleistocene)—Poorly sorted silt, sand, and gravel. Locally contains abundant angular pebbles, cobbles, and boulders derived from nearby high ground. Locally includes talus, slopewash, and landslide deposits.
- Tu** **Unita Formation (Eocene)**—Formed mainly from the clastic sediments of a generally northward-prograding deltaic complex that ultimately filled the Eocene lake in which the Green River Formation was deposited. Much of the Unita consists of southward-thinning wedges composed chiefly of sandstone and siltstone that interfinger with northward-thinning tongues of marlstone of the Green River Formation. The intertonguing Unitu-Green River sequence below the main body of the Unitu is divided into two map units which are described separately below. The Unitu Formation, including its tongues, is mostly brown weathering sandstone and siltstone, but also includes marlstone, mudstone, shale, oil shale, minor limestone, and thin tuff beds. The sandstone beds, highly variable in lithology, range from very fine to very coarse grained, and are locally conglomeratic. Sandstone beds are generally massive or poorly bedded, but in a few areas are crossbedded to parallel bedded. Siltstone beds and fine-grained sandstone beds are tuffaceous, locally argillaceous, calcitic, and commonly contain fragments of carbonized fossil plants. Siltstone beds are variably muddy. Marlstone and shale beds are gray to greenish-gray. The marlstone beds are light gray, variably silty, and locally contain oil shale. The lithology is similar to that of marlstone beds of the Parashute Creek Member of the Green River Formation. Minor thin limestone beds are associated with the marlstone beds. Some sandstone and siltstone beds are resistant, generally where more strongly cemented by calcite, and form prominent cliffs or ledges. Others are soft, poorly cemented, and friable, and weather to slopes. Paleosol blocks are fairly common, especially where resistant sandstone or siltstone bodies overlie marlstone.
- Tu** **Main body of Unitu Formation**—The uppermost part of the Unitu in the map area includes fairly abundant marlstone beds similar in lithology to the underlying tongues of the Green River Formation. Most (not all) of these marlstone beds are, however, lenticular and are not regarded as tongues of the Green River. The basal contact of the main body of the Unitu is placed at the top of the stratigraphically highest mapped tongue of the Green River or at the top of the Parashute Creek Member where tongues of the Green River are absent. Thus the basal contact lies at various stratigraphic horizons in the map area. The lenticular marlstone beds in the main body locally contain oil shale which is relatively rich in places, but these oil-shale beds are generally thin, and like the enclosing marlstone beds, are lenticular, and of no present economic value. In the Desert Gulch quadrangle (Johnson, 1981), map unit Tu is a paleosol deposit of Eocene age and includes highly contorted rocks of the Unitu Formation as well as marlstone tongues of the Green River Formation. The entire unit is here arbitrarily included in the main body of the Unitu. Smaller paleosol blocks are present elsewhere, especially at the basal contact of the main body.
- Tgs** **Intertonguing Unitu and Green River Formations (Eocene)**—The thick stratigraphic sequence overlying the Parashute Creek Member of the Green River Formation and underlying the unit here designated as the main body of the Unitu Formation consists of completely intertonguing units of both formations. On the constituent 7 1/2-minute maps, tongues of the Unitu are unnamed. Some are designated by letters in ascending alphabetical order; others are designated simply as Tu. Tongues of the Green River include two formally named tongues, and several informally named tongues. The Green River tongues range laterally, generally southward, with other Green River tongues or with the Parashute Creek Member of the Green River Formation. Owing to limitations of map scale, individual tongues are not shown on this map. The intertonguing Unitu-Green River sequence is here divided into two map units: upper group (Tg) and lower group (Tg). The Unitu tongues are generally as described above: mostly brown weathering sandstone and siltstone, lesser marlstone including oil shale, mudstone, shale, and minor limestone. These tongues gradually become thinner, finer grained, and more argillaceous toward their southward termination. The Green River tongues are mostly marlstone, including oil shale, of essentially the same lithology as the Parashute Creek Member of the Green River Formation into which they merge. In general, oil-shale beds become thicker and oil-shale values increase to the south. Some of the Green River tongues are largely oil shale where they merge with the Parashute Creek Member. The Green River tongues locally include sandstone and siltstone beds.
- Tgt** **Upper group of tongues of Unitu and Green River Formations**—Includes as many as ten tongues of the Unitu and Green River as mapped separately on the constituent 7 1/2-minute maps (table 1). No formally named tongues are included. Informally named Green River tongues in the sequence are the marlstone at Silver Ridge, Sleepy Ridge, Bull Fork, Barnes Ridge, and Jackrabtree Ridge (table 1, map units Tgk, Tgl, Tgt, Tgh, and Tgi). The stratigraphically highest part of the upper group is the marlstone at Skinner Ridge (table 1, map unit Tgi), present only in the southwestern part of the map area. In much of the area, the basal contact of the upper group is placed at the base of a widespread Unitu tongue which overlies the Stewart Gulch Tongue of the Green River Formation, or laterally equivalent strata. Where this Unitu tongue is absent or not mapped separately, the contact is arbitrarily moved to a different stratigraphic horizon toward their southward termination.
- Tg** **Lower group of tongues of Unitu and Green River Formations**—Includes as many as six tongues of the Unitu and Green River as mapped separately on the constituent 7 1/2-minute quadrangle maps (table 1). Includes two formally named tongues of the Green River Formation, the Stewart Gulch and Cough Creek Tongues; both are widespread and distinctive in the map area. The Stewart Gulch Tongue consists of light-gray dolomitic, variably silty marlstone, including oil shale which increases in content to the south; it also includes some fine-grained sandstone. The Cough Creek Tongue is mostly light-gray marlstone but it commonly contains beds of siltstone, sandstone, and locally oil shale. The base of the lower group is placed at the base of the lowermost Unitu tongue which generally is the tongue underlying the Cough Creek Tongue of the Green River Formation.
- Tm** **Green River Formation (Eocene)**—Sediments deposited in a variety of depositional environments, mostly lacustrine and marginal lacustrine to fluvial.
- Tgs** **Parashute Creek Member**—Mostly dolomitic marlstone, oil shale, and some dolomitic shale and claystone in the lower part. Also contains several beds of gray to light-brown siltstone and sandstone, and numerous very thin beds of micaceous silt. Sparsely bedded beds present in lower part. Marlstone is massive to platy, gray to light grayish brown. Oil shale is thin, parallel bedded to lenticular, medium to dark brown. Beds of marlstone and oil shale weather light gray. The richest oil-shale beds weather light bluish gray. Clay shale is brownish gray, very thin bedded to thinly laminated, locally weathers weathering. Potentially valuable oil shale is present mostly in oil-shale zones R3, L3, R4, L4, R5, L5, R6, Mahogany zone (Hall, 1975, 1988; Johnson, 1981; and O'Sullivan and Hall, 1987), and a sequence of mostly lesser oil shale as much as 300-400 ft (90-120 m) thick above the Mahogany zone. The marlstone and oil shale are relatively resistant and form steep cliffs capping canyon walls. Thickness of the Parashute Creek Member in outcrop ranges from about 900 to 1,200 ft (270-370 m).
- Tgt** **Mahogany ledge**—Top of a rich oil-shale zone in the Parashute Creek Member. The term Mahogany ledge is used for outcropping Mahogany zone. Thickness ranges from about 60 ft (18 m) in the southwest part of the map area to about 130 ft (40 m) in the northeast part.
- Tgk** **Douglas Creek Member**—Mostly dark gray to brown claystone, locally fissile kerogen-rich gray shale, dolomitic shale, and marlstone. Contains silty marlstone and claystone, several thin oil-shale beds, a few brown-weathering siltstone and sandstone beds, and several thin limestone beds. In much of the map area, where the Garden Gulch Member lies directly on the Wasatch Formation, the basal bed is the Long Point Bed (Johnson, 1984, p. 11-16), a widespread transgressive lacustrine unit, which has a maximum thickness of as much as 12 ft (3.7 m); it includes gastropods, ostracod, and calcitic limestone and sandstone, and locally silty claystone, and shale. The Garden Gulch Member grades eastward into the upper part of the Anvil Points Member (Tgi). This gradation is characterized by an increase in the number and thickness of sandstone beds, and the Garden Gulch is abruptly terminated along a facies boundary in Wheeler Gulch in the southwestern part of the map area. The Garden Gulch is mostly nonresistant and forms slopes. Thickness of the Garden Gulch in Parashute Creek drainage in the southwestern part of the area about 680-750 ft (210-230 m). Thickness in Clear Creek, Brook Creek, and Roan Creek drainages in the southwestern part of the area about 180-220 ft (55-67 m).
- Tgi** **Anvil Points Member**—In the extreme southeastern part of the area, where the Garden Gulch Member is absent, the Anvil Points Member is mostly light gray to brown fine to coarse-grained locally conglomeratic sandstone, and interbedded siltstone and shale. Also contains minor light brown and yellowish-gray oolitic limestone, and a few beds of gray marlstone in the upper part; maximum thickness about 1,200 ft (370 m). In the drainage of Parashute Creek and elsewhere where the Garden Gulch Member is present, the Anvil Points is mostly gray to brown-weathering kerogen-rich shale and lesser brown-weathering fine to medium-grained sandstone; thickness about 300-400 ft (90-120 m). The abrupt eastward thickening of the Anvil Points is at the expense of the Garden Gulch Member which grades laterally eastward into the upper part of the Anvil Points. The basal unit of the Anvil Points Member is the Long Point Bed, a widespread transgressive lacustrine unit (Johnson, 1984, p. 11-16) which consists mostly of oolitic and calcitic sandstone in the map area.
- Tgh** **Cow Ridge Member**—Mostly dark gray clay shale, dark-brown carbonaceous shale, very thin coal beds, and a few thin beds of sandstone and siltstone. Gastropods and pelecypods are locally abundant. Exposed only along Roan Creek in the southwestern part of the map area. Basal part of member covered. Thickness of exposed beds about 200 ft (60 m).
- Tgi** **Wasatch Formation (Paleocene and Eocene)**—Rocks of fluvial and paludal origin. Exposed rocks are probably Shire Member of the Wasatch. Rocks of Paleocene age present only in subsurface in the map area.
- Tm** **Main body**—Varicolored red, purple, lavender, gray and grayish-yellow claystone, shale, silty shale, and siltstone; brown and gray fine to coarse-grained lenticular channel-filling sandstone. Only upper part exposed. Nonresistant; forms gentle slopes; beds to slumps. Maximum thickness of exposed beds about 300 ft (90 m).
- Tw** **Tongue of Wasatch**—Mostly varicolored red, purple, maroon, yellowish-gray, and gray claystone and mudstone. Also contains some beds of fine to medium-grained lenticular sandstone. Thickness of exposed beds about 240 ft (73 m).
