DESCRIPTION OF MAP UNITS

Qa1 ALLUVIUM (HOLOCENE)—Unconsolidated silt, sand, and gravel

Q1a LANDSLIDE DEPOSITS (PLEISTOCENE)—Found only on north side of White River

Tgt TERRACE DEPOSITS (PLEISTOCENE)—Mostly cobbles and pebbles in a sandy matrix; line cemented and generally overlain by as much as 10 ft (3 m) of sandy silt. Cobbles and pebbles are derived mostly from Paleozoic sandstone, siltstone, and limestone, some clasts of volcanic rocks, and a minor number from from plutonic, igneous, and metamorphic rocks. At least three distinct terrace levels occur in the map area

Tu UNTA FORMATION (EOCENE)—Mostly sandstone; tuffaceous, brown to yellowish gray, medium to coarse grained, massive; several tongues of the Green River Formation consisting of marlstone and early siltstone included in map unit. Unta Formation replaces the abandoned term Evacuation Creek Member of the Green River Formation in Piceance Creek basin (Cashlow and Donnell, 1974). The thickness of the formation ranges from about 1,050 ft (320 m) in the southeast corner of the quadrangle to about 675 ft (206 m) in the southeast corner, the top being the present surface of erosion

Tg GREEN RIVER FORMATION (EOCENE)—Tongues of Green River Formation described in Duncan others (1973)

Tgt Thirtymile Creek Tongue—Mostly light-gray marlstone and silt marlstone; contains a thin ostracodal limestone bed about 20 ft (6 m) above the base and a thin brachiopod limestone bed near the base. The tongue is exposed on the south side of Dry Fork of Piceance Creek, along the southern boundary of the quadrangle, and maps one hill north of Dry Fork near the center W 1/2 NE 1/4 sec. 3, T. 1 S., R. 96 W. Thickness about 60 ft (18 m)

Tgd Dry Fork Tongue—Light-greenish-gray marlstone, silty marlstone, and calcareous siltstone. Contacts with the overlying and underlying Unta Formation are gradational. Brown fossil wood commonly occurs at the basal contact with the underlying sandstone. Thickness varying from about 70 ft (21 m) in the southeastern part of the quadrangle to 30 ft (9 m) in the southeastern part

Tgy Yellow Creek Tongue—Mostly light-greenish-gray marlstone with varying amounts of sandstone, siltstone, and silty marlstone; locally contains a thin oil-shale bed at the top and a siltstone ledge near the middle. The unit thins eastward from 65 ft (20 m) along the western boundary of the quadrangle to about 20 ft (6 m) in the northern part of sec. 34, T. 1 N., R. 96 W., but rapidly thickens again southeastward to about 100 ft (30 m) in the NE 1/4 sec. 2, T. 1 N., R. 96 W. At this locality it comprises two marlstone sequences separated by a light-brown sandstone bed 27 ft (9 m) thick. The upper marlstone sequence is about 38 ft (11.6 m) thick. It is soft and greenish gray in the upper part, but porcellaneous and grayish white in the lower part. The lower marlstone sequence is about 27 ft (9 m) thick and is entirely light gray. In the southeastern area of the map only the base is shown

Tgp Parachute Creek Member—Oil shale and marlstone, several tuff beds, and a few siltstone beds. The oil shale is light brown to brownish black and weathers gray to bluish gray. Fresh and weathered surfaces of marlstone are light gray. Five of the tuff beds are relatively thick and persist throughout the map area. All are shown in the columnar section, but only the lowermost of these (yellow tuff bed; yt) is shown on the map. The other four tuffs are light gray to yellowish gray, 0.5-1 ft (15-30 cm) thick and occur 230 ft (70 m) above the top of the Mahogany ledge (M), 30 ft (9 m) below the top of the Mahogany ledge, 3-7 ft (1-2 m) above the base of the Mahogany ledge, and about 40 ft (12 m) below the B-groove (B). The upper three tuffs are equivalent to beds 202, 175, and 134, and the lowermost (yt) is equivalent to bed 22 of Brobst and Tucker (1973, p. 14-16, 18). The correlation of the tuff that occurs about 40 ft (12 m) below the B-groove with the stratigraphic section measured by Brobst and Tucker is uncertain. The eastern part of the map area the Parachute Creek Member is divided into upper (Tgpu) and lower (Tgpl) parts by the upper part of the Anvil Points Member (Tgau). Thickness of member about 1,160 ft (354 m) at the surface along Piceance Creek, but unit thickens in subsurface to about 1,340 ft (409 m) in the Tintic Standard Mining Co. dry hole drilled in sec. 36, T. 1 N., R. 97 W. (see columnar section)

Tgpu Upper part—Extends to about 300 ft (92 m) above the base of the B-groove; thickness about 790-850 ft (241-259 m)

Tgpl Mahogany ledge—Top of rich oil-shale zone which forms conspicuous ledge about 440-275 ft (134-84 m) below the top of the Parachute Creek Member with the interval decreasing toward the southeast. Persistent irregularly bedded tuffs 0.5-1 ft (15-30 cm) thick occur 30 ft (9 m) below the top and about 3-7 ft (1-2 m) above the base (beds 174 and 134 of Brobst and Tucker, 1973, p. 15-16). The ledge is about 165 ft (50 m) thick in an east-west direction across the map area, but thickens southward in the subsurface to about 230 ft (70 m) in the Tintic Standard Mining Co. dry hole in sec. 36, T. 1 N., R. 97 W.

Tg B-groove—The B-groove comprises a lean oil-shale and barren marlstone zone directly beneath the Mahogany ledge. The basal bed of the B-groove is distinctive; it consists of kerogen-rich dolomite that makes a ledge 0.5-1 ft (15-30 cm) thick; the ledge is hard, brittle, jointed, and weathers into fingerlike projections; it occurs about 38-44 ft (11.6-13.5 m) above a biotite-bearing irregularly bedded tuff 0.5-1 ft (15-30 cm) thick. The correlation of this tuff with the stratigraphic section measured by Brobst and Tucker (1973) is uncertain. The B-groove becomes more barren, and gets sandy eastward; it thins, becomes less barren and is less sandy southward. Thickness 40-55 ft (12-17 m)

Tg Lower part—Mostly medium-grade oil shale, medium-bedded to massive, weathers light gray; thickness ranges from about 40 ft (12 m) in the NE 1/4 SE 1/4 sec. 25, T. 1 N., R. 96 W., on the north side of the White River, to about 325 ft (82 m) near where it merges with the upper part of the member near the center of sec. 17, T. 1 N., R. 96 W. Yellow tuff bed—Tuff, 0.1-0.2 ft (3-6 cm) thick, weathers light yellow, occurs 1.25-2 ft (38-61 cm) above the base of a 10-20 ft (3-6 m) thick ledge-forming medium-grade oil-shale sequence whose weathered surfaces are studied by rusty-orange dolomitic low-grade oil-shale fragments. This ledge is split into two parts by a sandy dolomite or sandstone bed 1-11 ft (30 cm-3.6 m) thick. Consequently, it is informally referred to as the "split bench." Throughout the map area the split bench directly overlies a greenish-gray claystone bed 1-5 ft (30 cm-1.5 m) thick which grades downward into a barren light-gray-weathering marlstone sequence, making a hard-surfaced slope nearly bare of vegetation. This barren marlstone sequence in turn grades downward into brown paper shale that makes soft sage-, shrub-, and grass-covered slopes in the upper part of the Garden Gulch Member. The contact of the barren marlstone sequence with the brown paper shale is the contact of the Parachute Creek with the Garden Gulch Member. It is easily observed in the good exposures on either side of Piceance Creek, but very difficult or impossible to detect in the heavily vegetated more easterly part of the map area. For that reason the yellow tuff bed near the base of the split bench is shown on the map rather than the actual contact. The base of the split bench ranges from 20-70 ft (6-21 m) above the base of the Parachute Creek Member from east to west across the map area and appears to be as much as 260 ft (82 m) above the base of the member in the southwestern part of the mapped area in well 36

Tg Garden Gulch Member—Mostly brown paper shale-siltstone clayey noncalcareous oil shale containing a few sandstone and dolomite beds generally 1 ft (30 cm) or less thick; includes two beds of dolomitic medium-grade oil shale that make gray-weathering ledges in a zone 80-100 ft (24-30 m) below the top. The member includes several beds of ostracodal, oolitic, and pisolitic sandstone and limestone in the eastern part of the area. Throughout most of the area, the base of the Garden Gulch is placed at the top of a sandstone ledge about 30 ft (9 m) above the top of a zone of desiccated dolomite concretions (c) that 10-16 ft (3-5 m) thick. Locally, however, it is not feasible to map either the ledge or the concretions, and the top of the pisolite ledge (ps), about 100 ft (30 m) stratigraphically higher, was arbitrarily mapped as the base of the member. The change from the lower to the upper mapping horizon was made along the White River in the NW 1/4 sec. 15, T. 1 N., R. 96 W. The member is 300-400 ft (91-122 m) thick on the surface, and thickens to about 450 ft (137 m) in well 36

First algal silty stromatolites, spheroidal or matlike, as much as 1 ft (30 cm) thick, which overlie a medium-grained sandstone ledge as much as 45 ft (14 m) thick. Locally the stromatolites are inconspicuous or absent; only the top of the ledge is shown; in this quadrangle it crops out only on the north side of the White River. Pisolite ledge—A light-gray sandstone ledge that becomes successively pisolitic, oolitic, and ostracodal in the upper 12-15 ft (3.5-4.5 m). Algal stromatolites are common in the upper 1 ft (30 cm). A conspicuous layer of pisolites about 0.5 ft (15 cm) thick under the stromatolites give the ledge its name. In this quadrangle the pisolite ledge crops out only along the White River in the eastern part of the area. It was not recognized in any exposures farther to the west. It extends from the eastern margin of the quadrangle, where it is about 40 ft (12 m) thick, to the SW 1/4 SE 1/4 sec. 15, T. 1 N., R. 96 W., where it is about 10 ft (3 m) thick

Anvil Points Member

Tgau Upper part—Mostly sandstone, siltstone, and claystone; a few beds of marlstone and low-grade oil shale. The sandstone is gray, medium bedded to massive, and forms ledges that commonly are ripple marked; claystone is olive gray, medium bedded to massive, and forms slopes. Siltstone is gray to tan and forms slopes. The unit is about 185 ft (50 m) thick at the eastern boundary of the quadrangle, but thins to the west and disappears within the Parachute Creek Member near the NW 1/4 SE 1/4 sec. 17, T. 1 N., R. 97 W.

Tg Lower part—Mostly sandstone and siltstone; some claystone and shale; contains many beds of ostracodal sandstone and ostracodal and oolitic limestone. The sandstone is light yellowish gray, fine to medium grained, medium bedded to massive, and forms ledges. The tan siltstone and light-gray claystone generally form slopes. All the limestone and clay sandstone beds weather rusty brown and make ledges. Thickness of the unit about 100-500 ft (30-152 m); unit thins to the southwest. The contact of the Anvil Points Member with the underlying Wasatch Formation is gradational and intertonguing; it is placed at the approximate change from cliff-forming sandstone above to slope-forming variegated claystone and siltstone below

Desiccated concretion zone—Concretions are very fine grained silty dolomite that weathers orange yellow to greenish yellow; they are discoidal and as much as 8 in. (20 cm) long and 3 in. (7.6 cm) thick. The surface of most of them shows weathered shrinkage cracks a few millimetres wide. Along Piceance Creek the concretions occur in a claystone and clayey siltstone sequence about 30-45 ft (9-14 m) below the base of the Garden Gulch Member; in the eastern part of the area the concretions are about 10 ft (3 m) above the base of the member. North of White River, concretion zone overlies a thin tuff containing yellow amorphous spherulites. This concretion-bearing claystone and siltstone sequence appears to correlate with the orange marked bed in the subsurface. Lower ostracodal limestone—The lower ostracodal limestone is the uppermost prominent bed in a sequence of gray, ostracodal, and oolitic limestone and sandy limestone ledges separated by slopes of gray to brown medium-grained sandstone. The lower ostracodal limestone is 1-1 ft (30-10 cm) thick; in this quadrangle it crops out only on the north side of the White River. Total thickness of the sequence is about 20 ft (6 m)

Tv WASATCH FORMATION (EOCENE)—Mainly variegated claystone and siltstone containing lenses and channels of medium- to coarse-grained crossbedded sandstone. Throughout most of the map area a few thin beds of carbonaceous shale or siltstone occur in the upper part of the Wasatch, generally within 20 ft (6 m) of the overlying basal cliff of the Anvil Points Member. The variegated beds consist principally of ocher-, light-purple, paled, light-gray, and light-grayish-green silty claystone and clayey siltstone. The sandstones are lenticular, channeled, and entirely of fluvial origin. The base is not exposed in the map area. A study of the samples in well 25 suggests that the Eocene-Paleocene boundary occurs at a depth of about 1,300 ft (396 m). This boundary is not apparent in electric logs of well 25. Nevertheless the position of the boundary was estimated in well 3 and in two wells in the adjacent Buckskin Point quadrangle. From these control points thicknesses of Eocene part of the Wasatch were estimated and projected into the cross section north of the White River; it ranges from about 2,800 ft (853 m) near the White River, to about 3,350 ft (1,020 m) near the point A'. In hole 25, the thickness of the Paleocene part of the Wasatch rocks is estimated to be about 2,140 ft (652 m)

tion measured by Brobst and Tucker (1973) is uncertain. The B-groove thickness, becomes more barren, and gets sandy eastward; it thins, becomes less barren and is less sandy southward. Thickness 40-55 ft (12-17 m)

Lower part—Mostly medium-grade oil shale, medium-bedded to massive, weathers light gray; thickness ranges from about 40 ft (12 m) in the NE 1/4 SE 1/4 sec. 25, T. 1 N., R. 96 W., on the north side of the White River, to about 325 ft (82 m) near where it merges with the upper part of the member near the center of sec. 17, T. 1 N., R. 96 W. Yellow tuff bed—Tuff, 0.1-0.2 ft (3-6 cm) thick, weathers light yellow, occurs 1.25-2 ft (38-61 cm) above the base of a 10-20 ft (3-6 m) thick ledge-forming medium-grade oil-shale sequence whose weathered surfaces are studied by rusty-orange dolomitic low-grade oil-shale fragments. This ledge is split into two parts by a sandy dolomite or sandstone bed 1-11 ft (30 cm-3.6 m) thick. Consequently, it is informally referred to as the "split bench." Throughout the map area the split bench directly overlies a greenish-gray claystone bed 1-5 ft (30 cm-1.5 m) thick which grades downward into a barren light-gray-weathering marlstone sequence, making a hard-surfaced slope nearly bare of vegetation. This barren marlstone sequence in turn grades downward into brown paper shale that makes soft sage-, shrub-, and grass-covered slopes in the upper part of the Garden Gulch Member. The contact of the barren marlstone sequence with the brown paper shale is the contact of the Parachute Creek with the Garden Gulch Member. It is easily observed in the good exposures on either side of Piceance Creek, but very difficult or impossible to detect in the heavily vegetated more easterly part of the map area. For that reason the yellow tuff bed near the base of the split bench is shown on the map rather than the actual contact. The base of the split bench ranges from 20-70 ft (6-21 m) above the base of the Parachute Creek Member from east to west across the map area and appears to be as much as 260 ft (82 m) above the base of the member in the southwestern part of the mapped area in well 36

Tg Garden Gulch Member—Mostly brown paper shale-siltstone clayey noncalcareous oil shale containing a few sandstone and dolomite beds generally 1 ft (30 cm) or less thick; includes two beds of dolomitic medium-grade oil shale that make gray-weathering ledges in a zone 80-100 ft (24-30 m) below the top. The member includes several beds of ostracodal, oolitic, and pisolitic sandstone and limestone in the eastern part of the area. Throughout most of the area, the base of the Garden Gulch is placed at the top of a sandstone ledge about 30 ft (9 m) above the top of a zone of desiccated dolomite concretions (c) that 10-16 ft (3-5 m) thick. Locally, however, it is not feasible to map either the ledge or the concretions, and the top of the pisolite ledge (ps), about 100 ft (30 m) stratigraphically higher, was arbitrarily mapped as the base of the member. The change from the lower to the upper mapping horizon was made along the White River in the NW 1/4 sec. 15, T. 1 N., R. 96 W. The member is 300-400 ft (91-122 m) thick on the surface, and thickens to about 450 ft (137 m) in well 36

First algal silty stromatolites, spheroidal or matlike, as much as 1 ft (30 cm) thick, which overlie a medium-grained sandstone ledge as much as 45 ft (14 m) thick. Locally the stromatolites are inconspicuous or absent; only the top of the ledge is shown; in this quadrangle it crops out only on the north side of the White River. Pisolite ledge—A light-gray sandstone ledge that becomes successively pisolitic, oolitic, and ostracodal in the upper 12-15 ft (3.5-4.5 m). Algal stromatolites are common in the upper 1 ft (30 cm). A conspicuous layer of pisolites about 0.5 ft (15 cm) thick under the stromatolites give the ledge its name. In this quadrangle the pisolite ledge crops out only along the White River in the eastern part of the area. It was not recognized in any exposures farther to the west. It extends from the eastern margin of the quadrangle, where it is about 40 ft (12 m) thick, to the SW 1/4 SE 1/4 sec. 15, T. 1 N., R. 96 W., where it is about 10 ft (3 m) thick

Anvil Points Member

Tgau Upper part—Mostly sandstone, siltstone, and claystone; a few beds of marlstone and low-grade oil shale. The sandstone is gray, medium bedded to massive, and forms ledges that commonly are ripple marked; claystone is olive gray, medium bedded to massive, and forms slopes. Siltstone is gray to tan and forms slopes. The unit is about 185 ft (50 m) thick at the eastern boundary of the quadrangle, but thins to the west and disappears within the Parachute Creek Member near the NW 1/4 SE 1/4 sec. 17, T. 1 N., R. 97 W.

Tg Lower part—Mostly sandstone and siltstone; some claystone and shale; contains many beds of ostracodal sandstone and ostracodal and oolitic limestone. The sandstone is light yellowish gray, fine to medium grained, medium bedded to massive, and forms ledges. The tan siltstone and light-gray claystone generally form slopes. All the limestone and clay sandstone beds weather rusty brown and make ledges. Thickness of the unit about 100-500 ft (30-152 m); unit thins to the southwest. The contact of the Anvil Points Member with the underlying Wasatch Formation is gradational and intertonguing; it is placed at the approximate change from cliff-forming sandstone above to slope-forming variegated claystone and siltstone below

Desiccated concretion zone—Concretions are very fine grained silty dolomite that weathers orange yellow to greenish yellow; they are discoidal and as much as 8 in. (20 cm) long and 3 in. (7.6 cm) thick. The surface of most of them shows weathered shrinkage cracks a few millimetres wide. Along Piceance Creek the concretions occur in a claystone and clayey siltstone sequence about 30-45 ft (9-14 m) below the base of the Garden Gulch Member; in the eastern part of the area the concretions are about 10 ft (3 m) above the base of the member. North of White River, concretion zone overlies a thin tuff containing yellow amorphous spherulites. This concretion-bearing claystone and siltstone sequence appears to correlate with the orange marked bed in the subsurface. Lower ostracodal limestone—The lower ostracodal limestone is the uppermost prominent bed in a sequence of gray, ostracodal, and oolitic limestone and sandy limestone ledges separated by slopes of gray to brown medium-grained sandstone. The lower ostracodal limestone is 1-1 ft (30-10 cm) thick; in this quadrangle it crops out only on the north side of the White River. Total thickness of the sequence is about 20 ft (6 m)

Tv WASATCH FORMATION (EOCENE)—Mainly variegated claystone and siltstone containing lenses and channels of medium- to coarse-grained crossbedded sandstone. Throughout most of the map area a few thin beds of carbonaceous shale or siltstone occur in the upper part of the Wasatch, generally within 20 ft (6 m) of the overlying basal cliff of the Anvil Points Member. The variegated beds consist principally of ocher-, light-purple, paled, light-gray, and light-grayish-green silty claystone and clayey siltstone. The sandstones are lenticular, channeled, and entirely of fluvial origin. The base is not exposed in the map area. A study of the samples in well 25 suggests that the Eocene-Paleocene boundary occurs at a depth of about 1,300 ft (396 m). This boundary is not apparent in electric logs of well 25. Nevertheless the position of the boundary was estimated in well 3 and in two wells in the adjacent Buckskin Point quadrangle. From these control points thicknesses of Eocene part of the Wasatch were estimated and projected into the cross section north of the White River; it ranges from about 2,800 ft (853 m) near the White River, to about 3,350 ft (1,020 m) near the point A'. In hole 25, the thickness of the Paleocene part of the Wasatch rocks is estimated to be about 2,140 ft (652 m)

tion measured by Brobst and Tucker (1973) is uncertain. The B-groove thickness, becomes more barren, and gets sandy eastward; it thins, becomes less barren and is less sandy southward. Thickness 40-55 ft (12-17 m)

Lower part—Mostly medium-grade oil shale, medium-bedded to massive, weathers light gray; thickness ranges from about 40 ft (12 m) in the NE 1/4 SE 1/4 sec. 25, T. 1 N., R. 96 W., on the north side of the White River, to about 325 ft (82 m) near where it merges with the upper part of the member near the center of sec. 17, T. 1 N., R. 96 W. Yellow tuff bed—Tuff, 0.1-0.2 ft (3-6 cm) thick, weathers light yellow, occurs 1.25-2 ft (38-61 cm) above the base of a 10-20 ft (3-6 m) thick ledge-forming medium-grade oil-shale sequence whose weathered surfaces are studied by rusty-orange dolomitic low-grade oil-shale fragments. This ledge is split into two parts by a sandy dolomite or sandstone bed 1-11 ft (30 cm-3.6 m) thick. Consequently, it is informally referred to as the "split bench." Throughout the map area the split bench directly overlies a greenish-gray claystone bed 1-5 ft (30 cm-1.5 m) thick which grades downward into a barren light-gray-weathering marlstone sequence, making a hard-surfaced slope nearly bare of vegetation. This barren marlstone sequence in turn grades downward into brown paper shale that makes soft sage-, shrub-, and grass-covered slopes in the upper part of the Garden Gulch Member. The contact of the barren marlstone sequence with the brown paper shale is the contact of the Parachute Creek with the Garden Gulch Member. It is easily observed in the good exposures on either side of Piceance Creek, but very difficult or impossible to detect in the heavily vegetated more easterly part of the map area. For that reason the yellow tuff bed near the base of the split bench is shown on the map rather than the actual contact. The base of the split bench ranges from 20-70 ft (6-21 m) above the base of the Parachute Creek Member from east to west across the map area and appears to be as much as 260 ft (82 m) above the base of the member in the southwestern part of the mapped area in well 36

Tg Garden Gulch Member—Mostly brown paper shale-siltstone clayey noncalcareous oil shale containing a few sandstone and dolomite beds generally 1 ft (30 cm) or less thick; includes two beds of dolomitic medium-grade oil shale that make gray-weathering ledges in a zone 80-100 ft (24-30 m) below the top. The member includes several beds of ostracodal, oolitic, and pisolitic sandstone and limestone in the eastern part of the area. Throughout most of the area, the base of the Garden Gulch is placed at the top of a sandstone ledge about 30 ft (9 m) above the top of a zone of desiccated dolomite concretions (c) that 10-16 ft (3-5 m) thick. Locally, however, it is not feasible to map either the ledge or the concretions, and the top of the pisolite ledge (ps), about 100 ft (30 m) stratigraphically higher, was arbitrarily mapped as the base of the member. The change from the lower to the upper mapping horizon was made along the White River in the NW 1/4 sec. 15, T. 1 N., R. 96 W. The member is 300-400 ft (91-122 m) thick on the surface, and thickens to about 450 ft (137 m) in well 36

First algal silty stromatolites, spheroidal or matlike, as much as 1 ft (30 cm) thick, which overlie a medium-grained sandstone ledge as much as 45 ft (14 m) thick. Locally the stromatolites are inconspicuous or absent; only the top of the ledge is shown; in this quadrangle it crops out only on the north side of the White River. Pisolite ledge—A light-gray sandstone ledge that becomes successively pisolitic, oolitic, and ostracodal in the upper 12-15 ft (3.5-4.5 m). Algal stromatolites are common in the upper 1 ft (30 cm). A conspicuous layer of pisolites about 0.5 ft (15 cm) thick under the stromatolites give the ledge its name. In this quadrangle the pisolite ledge crops out only along the White River in the eastern part of the area. It was not recognized in any exposures farther to the west. It extends from the eastern margin of the quadrangle, where it is about 40 ft (12 m) thick, to the SW 1/4 SE 1/4 sec. 15, T. 1 N., R. 96 W., where it is about 10 ft (3 m) thick

Anvil Points Member

Tgau Upper part—Mostly sandstone, siltstone, and claystone; a few beds of marlstone and low-grade oil shale. The sandstone is gray, medium bedded to massive, and forms ledges that commonly are ripple marked; claystone is olive gray, medium bedded to massive, and forms slopes. Siltstone is gray to tan and forms slopes. The unit is about 185 ft (50 m) thick at the eastern boundary of the quadrangle, but thins to the west and disappears within the Parachute Creek Member near the NW 1/4 SE 1/4 sec. 17, T. 1 N., R. 97 W.

Tg Lower part—Mostly sandstone and siltstone; some claystone and shale; contains many beds of ostracodal sandstone and ostracodal and oolitic limestone. The sandstone is light yellowish gray, fine to medium grained, medium bedded to massive, and forms ledges. The tan siltstone and light-gray claystone generally form slopes. All the limestone and clay sandstone beds weather rusty brown and make ledges. Thickness of the unit about 100-500 ft (30-152 m); unit thins to the southwest. The contact of the Anvil Points Member with the underlying Wasatch Formation is gradational and intertonguing; it is placed at the approximate change from cliff-forming sandstone above to slope-forming variegated claystone and siltstone below

Desiccated concretion zone—Concretions are very fine grained silty dolomite that weathers orange yellow to greenish yellow; they are discoidal and as much as 8 in. (20 cm) long and 3 in. (7.6 cm) thick. The surface of most of them shows weathered shrinkage cracks a few millimetres wide. Along Piceance Creek the concretions occur in a claystone and clayey siltstone sequence about 30-45 ft (9-14 m) below the base of the Garden Gulch Member; in the eastern part of the area the concretions are about 10 ft (3 m) above the base of the member. North of White River, concretion zone overlies a thin tuff containing yellow amorphous spherulites. This concretion-bearing claystone and siltstone sequence appears to correlate with the orange marked bed in the subsurface. Lower ostracodal limestone—The lower ostracodal limestone is the uppermost prominent bed in a sequence of gray, ostracodal, and oolitic limestone and sandy limestone ledges separated by slopes of gray to brown medium-grained sandstone. The lower ostracodal limestone is 1-1 ft (30-10 cm) thick; in this quadrangle it crops out only on the north side of the White River. Total thickness of the sequence is about 20 ft (6 m)

Tv WASATCH FORMATION (EOCENE)—Mainly variegated claystone and siltstone containing lenses and channels of medium- to coarse-grained crossbedded sandstone. Throughout most of the map area a few thin beds of carbonaceous shale or siltstone occur in the upper part of the Wasatch, generally within 20 ft (6 m) of the overlying basal cliff of the Anvil Points Member. The variegated beds consist principally of ocher-, light-purple, paled, light-gray, and light-grayish-green silty claystone and clayey siltstone. The sandstones are lenticular, channeled, and entirely of fluvial origin. The base is not exposed in the map area. A study of the samples in well 25 suggests that the Eocene-Paleocene boundary occurs at a depth of about 1,300 ft (396 m). This boundary is not apparent in electric logs of well 25. Nevertheless the position of the boundary was estimated in well 3 and in two wells in the adjacent Buckskin Point quadrangle. From these control points thicknesses of Eocene part of the Wasatch were estimated and projected into the cross section north of the White River; it ranges from about 2,800 ft (853 m) near the White River, to about 3,350 ft (1,020 m) near the point A'. In hole 25, the thickness of the Paleocene part of the Wasatch rocks is estimated to be about 2,140 ft (652 m)

tion measured by Brobst and Tucker (1973) is uncertain. The B-groove thickness, becomes more barren, and gets sandy eastward; it thins, becomes less barren and is less sandy southward. Thickness 40-55 ft (12-17 m)

Lower part—Mostly medium-grade oil shale, medium-bedded to massive, weathers light gray; thickness ranges from about 40 ft (12 m) in the NE 1/4 SE 1/4 sec. 25, T. 1 N., R. 96 W., on the north side of the White River, to about 325 ft (82 m) near where it merges with the upper part of the member near the center of sec. 17, T. 1 N., R. 96 W. Yellow tuff bed—Tuff, 0.1-0.2 ft (3-6 cm) thick, weathers light yellow, occurs 1.25-2 ft (38-61 cm) above the base of a 10-20 ft (3-6 m) thick ledge-forming medium-grade oil-shale sequence whose weathered surfaces are studied by rusty-orange dolomitic low-grade oil-shale fragments. This ledge is split into two parts by a sandy dolomite or sandstone bed 1-11 ft (30 cm-3.6 m) thick. Consequently, it is informally referred to as the "split bench." Throughout the map area the split bench directly overlies a greenish-gray claystone bed 1-5 ft (30 cm-1.5 m) thick which grades downward into a barren light-gray-weathering marlstone sequence, making a hard-surfaced slope nearly bare of vegetation. This barren marlstone sequence in turn grades downward into brown paper shale that makes soft sage-, shrub-, and grass-covered slopes in the upper part of the Garden Gulch Member. The contact of the barren marlstone sequence with the brown paper shale is the contact of the Parachute Creek with the Garden Gulch Member. It is easily observed in the good exposures on either side of Piceance Creek, but very difficult or impossible to detect in the heavily vegetated more easterly part of the map area. For that reason the yellow tuff bed near the base of the split bench is shown on the map rather than the actual contact. The base of the split bench ranges from 20-70 ft (6-21 m) above the base of the Parachute Creek Member from east to west across the map area and appears to be as much as 260 ft (82 m) above the base of the member in the southwestern part of the mapped area in well 36

Tg Garden Gulch Member—Mostly brown paper shale-siltstone clayey noncalcareous oil shale containing a few sandstone and dolomite beds generally 1 ft (30 cm) or less thick; includes two beds of dolomitic medium-grade oil shale that make gray-weathering ledges in a zone 80-100 ft (24-30 m) below the top. The member includes several beds of ostracodal, oolitic, and pisolitic sandstone and limestone in the eastern part of the area. Throughout most of the area, the base of the Garden Gulch is placed at the top of a sandstone ledge about 30 ft (9 m) above the top of a zone of desiccated dolomite concretions (c) that 10-16 ft (3-5 m) thick. Locally, however, it is not feasible to map either the ledge or the concretions, and the top of the pisolite ledge (ps), about 100 ft (30 m) stratigraphically higher, was arbitrarily mapped as the base of the member. The change from the lower to the upper mapping horizon was made along the White River in the NW 1/4 sec. 15, T. 1 N., R. 96 W. The member is 300-400 ft (91-122 m) thick on the surface, and thickens to about 450 ft (137 m) in well 36

First algal silty stromatolites, spheroidal or matlike, as much as 1 ft (30 cm) thick, which overlie a medium-grained sandstone ledge as much as 45 ft (14 m) thick. Locally the stromatolites are inconspicuous or absent; only the top of the ledge is shown; in this quadrangle it crops out only on the north side of the White River. Pisolite ledge—A light-gray sandstone ledge that becomes successively pisolitic, oolitic, and ostracodal in the upper 12-15 ft (3.5-4.5 m). Algal stromatolites are common in the upper 1 ft (30 cm). A conspicuous layer of pisolites about 0.5 ft (15 cm) thick under the stromatolites give the ledge its name. In this quadrangle the pisolite ledge crops out only along the White River in the eastern part of the area. It was not recognized in any exposures farther to the west. It extends from the eastern margin of the quadrangle, where it is about 40 ft (12 m) thick, to the SW 1/4 SE 1/4 sec. 15, T. 1 N., R. 96 W., where it is about 10 ft (3 m) thick

Anvil Points Member

Tgau Upper part—Mostly sandstone, siltstone, and claystone; a few beds of marlstone and low-grade oil shale. The sandstone is gray, medium bedded to massive, and forms ledges that commonly are ripple marked; claystone is olive gray, medium bedded to massive, and forms slopes. Siltstone is gray to tan and forms slopes. The unit is about 185 ft (50 m) thick at the eastern boundary of the quadrangle, but thins to the west and disappears within the Parachute Creek Member near the NW 1/4 SE 1/4 sec. 17, T. 1 N., R. 97 W.

Tg Lower part—Mostly sandstone and siltstone; some claystone and shale; contains many beds of ostracodal sandstone and ostracodal and oolitic limestone. The sandstone is light yellowish gray, fine to medium grained, medium bedded to massive, and forms ledges. The tan siltstone and light-gray claystone generally form slopes. All the limestone and clay sandstone beds weather rusty brown and make ledges. Thickness of the unit about 100-500 ft (30-152 m); unit thins to the southwest. The contact of the Anvil Points Member with the underlying Wasatch Formation is gradational and intertonguing; it is placed at the approximate change from cliff-forming sandstone above to slope-forming variegated claystone and siltstone below

Desiccated concretion zone—Concretions are very fine grained silty dolomite that weathers orange yellow to greenish yellow; they are discoidal and as much as 8 in. (20 cm) long and 3 in. (7.6 cm) thick. The surface of most of them shows weathered shrinkage cracks a few millimetres wide. Along Piceance Creek the concretions occur in a claystone and clayey siltstone sequence about 30-45 ft (9-14 m) below the base of the Garden Gulch Member; in the eastern part of the area the concretions are about 10 ft (3 m) above the base of the member. North of White River, concretion zone overlies a thin tuff containing yellow amorphous spherulites. This concretion-bearing claystone and siltstone sequence appears to correlate with the orange marked bed in the subsurface. Lower ostracodal limestone—The lower ostracodal limestone is the uppermost prominent bed in a sequence of gray, ostracodal, and oolitic limestone and sandy limestone ledges separated by slopes of gray to brown medium-grained sandstone. The lower ostracodal limestone is 1-1 ft (30-10 cm) thick; in this quadrangle it crops out only on the north side of the White River. Total thickness of the sequence is about 20 ft (6 m)

Tv WASATCH FORMATION (EOCENE)—Mainly variegated claystone and siltstone containing lenses and channels of medium- to coarse-grained crossbedded sandstone. Throughout most of the map area a few thin beds of carbonaceous shale or siltstone occur in the upper part of the Wasatch, generally within 20 ft (6 m) of the overlying basal cliff of the Anvil Points Member. The variegated
