MINERAL RESOURCE POTENTIAL OF THE ORLEANS MOUNTAIN ROADLESS AREA, HUMBOLDT AND SISKIYOU COUNTIES, CALIFORNIA

SUMMARY REPORT

By

Mary M. Donato, J. Mitchell Linne, Robert C. Jachens, and David B. Smith

STUDIES RELATED TO WILDERNESS

Under the provisions of the Wilderness Act (Public Law 88-577, September 3, 1964) and related acts, the U.S. Geological Survey and the U.S. Bureau of Mines have been conducting mineral surveys of wilderness and primitive areas. Areas officially designated as "wilderness", "wild", or "canoe" when the act was passed were incorporated into the National Wilderness Preservation System, and some of them are presently being studied. The act provided that areas under consideration for wilderness designation should be studied for suitability for incorporation into the Wilderness System. The mineral surveys constitute one aspect of the suitability studies. The act directs that the results of such surveys are to be made available to the President and the Congress. This report discusses the results of a mineral survey of the Orleans Mountain Roadless Area (B5079), Humboldt and Siskiyou Counties, Klamath and Six Rivers National Forests, California. The Orleans Mountain Roadless Area was classified as a further planning area during the Second Roadless Area Review and Evaluation (RARE II) by the U.S. Forest Service, January 1979.

SUMMARY

The principal mineral resource in the Orleans Mountain Roadless Area (B5079) is gold. Gravel deposits along the Salmon River contain placer gold. Lode gold and associated silver are contained in quartz veins. Since the middle 1800's over 200 lode claims have been located in the study area, primarily in the Orleans and Red Cap mining districts; many placer claims have been located in the Salmon River district. Four placer patents totaling 230 acres were issued for claims on the Salmon River adjacent to the study area. Incomplete production records indicate 100 oz of gold and 30 oz of silver were produced from the Chilton mine between 1927 and 1940. Within the study area, the Potluck, Horn, and Bloomer placer mines contain 950,000 yd^3 of gold resources with range in values from $0.51 to $4.97 per yd^3, with gold valued at $400 per troy oz. These three deposits extend outside the study area to include a total resource of approximately 3.3 million yd^3. Resources of lode gold exist at mines in the northwestern and southwestern parts of the study area. The Red Cap Central and Chilton mines contain an estimated 16,000 tons of inferred marginal reserves with values between 0.26 and 0.62 oz gold per ton. Silver values range between 0.2 and 2 oz per ton. The Whitehorse and Whitmore Creek mines contain an estimated 46,000 tons of indicated and inferred subeconomic resources with values averaging 0.08 oz gold per ton. Mineral resource potential of individual properties is summarized in tables 1 and 2.

INTRODUCTION

The U.S. Geological Survey and the U.S. Bureau of Mines conducted a mineral resource assessment of the Orleans Mountain Roadless Area, Humboldt and Siskiyou Counties, Calif. Geologic mapping, geophysical surveys, and geochemical sampling were carried out by the U.S. Geological Survey during 1980 and 1981. The U.S. Bureau of Mines gathered data concerning mines, prospects, and mineralized areas during 1980. Humboldt and Siskiyou County records, U.S. Bureau of Land Management master title plats, and U.S. Forest Service files were searched for identification of mineral claims. U.S. Bureau of Mines library materials and production records were studied for further information on identified mines. Seventy-three lode samples, taken from mines, prospects, claims, and mineralized areas were analyzed by atomic-absorption and fire-assay methods. Several samples from each prospect were analyzed by semiquantitative spectrographic methods to determine the presence of unsuspected elements. One hundred thirteen placer samples were concentrated through a sluice in the field and analyzed at the U.S. Bureau of Mines placer lab in Spokane, Wash. Complete analyses are on file at the U.S. Bureau of Mines, Western Field Operations Center, Spokane, Wash.

The Orleans Mountain Roadless Area is located in the Salmon Mountains of northern California and comprises approximately 44,000 acres of land in the Klamath and Six Rivers National Forests (fig. 1). The area is bounded on the northeast by the Salmon River, on the northwest by the Klamath River, and adjoins the Salmon-Trinity Alps Wilderness to the south. It is an area of great relief and rugged terrain, ranging in elevation from approximately 500 ft near Somes Bar to nearly 6,200 ft above sea level at Orleans Mountain.

Access is provided by State Highway 96 (Klamath River Highway), the Salmon River road, and by numerous logging roads which skirt the boundaries of the study area. In addition, trails and fire breaks facilitate limited access by foot to many parts of the area.

GEOLOGY, GEOCHEMISTRY, AND GEOPHYSICS

PERTAINING TO MINERAL RESOURCE ASSESSMENT

GEOLOGY

The Orleans Mountain Roadless Area is located in the Klamath Mountains geologic province of northern California. Previous geologic studies were carried out by Hershey (1906) and Cashman (1979). A geologic map has been prepared by
granodioritic in composition and fall into two general intrusive rocks

Intrusive rocks

approximately lat 40°15' and 40°45', the Hayfork terrane intrusive relations with the Wooley Creek batholith. No fossils have been found in this area, the age of this unit elsewhere is known to be late Jurassic (Harper, 1980). 

The structurally lowest unit in the map area, the Galice Formation, belongs to the western Jurassic belt. Although no fossils have been found in this area, the age of this unit elsewhere is known to be late Jurassic (Harper, 1980). 

The Galice Formation in this region consists mainly of interlayered slate and metagraywacke, although greenstone is abundant locally. The Galice is separated from the overlying rocks by an eastward-dipping regional thrust fault called the Orleans fault (Hershey, 1911), which forms the base contact of the western Paleozoic and Triassic belt.

Western Jurassic belt (Galice Formation)

stream sediments proved to be the most useful in evaluating the study area. This sample medium contains the common ore-forming sulfide and oxide minerals as well as other nonmagnetic minerals (for example, berile, zircon, rutile, etc.). The concentrate medium also gives a greatly enhanced anomaly pattern because all of the more common rock-forming minerals (quartz and feldspar) that tend to dilute the anomalous geological bodies have been removed.

Scattered anomalies of gold, silver, tungsten, and tin were found in panned concentrates taken from streams draining the eastern slope of the Salmon Mountains. All of these streams flow into the Salmon River, which has been a major producer of placer gold (Koschmann and Bergendahl, 1968). One sample from just within the study-area boundary, taken from Boise Creek just below the confluence with the Little South Fork of Boise Creek, contained anomalous values for gold, silver, and arsenic. The sample also contained visible cinnabar (HGS).

In summary, the reconnaissance geochemical sampling of the study area revealed scattered anomalies based on the concentration of gold, tungsten, tin, arsenic, and mercury in the concentrates. This suite of elements is believed to be characteristic of lode and placer gold deposits.**

**GEOPHYSICS**

Gravity and aeromagnetic surveys were conducted over the Orleans Mountain Roadless Area and surrounding areas to supplement the geologic mapping and to aid in the assessment of the mineral resource potential of the area. The gravity data reflect density contrasts in the rocks underlying the area, and the magnetic data reflect the distribution of magnetic minerals, mainly magnetite, in the subsurface. Because the major rock units present in this area possess characteristic densities and magnetic properties, the geophysical data have been used to infer the distribution of rock units and the attitudes of boundaries between them.

The most prominent feature of the residual gravity field in the vicinity of the study area is a magnetic low centered 1 to 1.5 mi north of Salmon Mountain. This magnetic low lies north of a strong magnetic high associated with an ultramafic body to the south and the low most likely represents a polarization effect of the anomaly over this body.

**MINING DISTRICTS AND MINERALIZATION**

Three mining districts overlap the study area: the Salmon River, Orleans, and Red Cap districts.

**Salmon River district**

The Salmon River district encompasses the entire drainage of the Salmon River, an area of about 800 mi² (Koschmann and Bergendahl, 1968). That portion of the district between Lewis Creek and Parks of Salmon overlaps the east boundary of the study area, but no development has occurred within the study area. The portion of this district within the study area falls entirely within the Hayfork terrane.

Gold was discovered on the Salmon River in 1849 (Clark, 1970). From 1932 to 1959 the district's production totaled 18,868 oz of gold and 15,981 oz of silver (Koschmann and Bergendahl, 1968). According to U.S. Bureau of Mines files, the Bloomer, Horn, and Potluck (Knudson Bar) placer mines yielded over 12,000 oz of gold and 840 oz of silver before 1920. Small-scale placer mining continues.

In the portion of the district in the study area, three bench placers from 50 to 400 ft above the present river channel are found at both the Bloomer and Horn properties (fig. 3). One bench placer about 30 ft above the river channel is found at the Potluck property. These bench placers are often overlain by thick layers of slide material.

Bench placer deposits adjoin and extend into the study area along the west side of the Salmon River. As many as three bench placers have been mined adjacent to the study area at both the Bloomer and Horn mines. At several channel sample localities, gold values were found as much as 15 ft above bedrock, indicating that mineral deposition may have occurred as separate events without later reconcentration.

Bench placers on the Potluck, Horn, and Bloomer placer property contain estimated 224,000 yd³ of indicated and inferred reserves averaging $4.97 per yd³, 871,000 yd³ of indicated subeconomic resources, and 2.1 million yd³ of inferred subeconomic resources with values ranging from $3.51 to $2.49 per yd³. A gold value of $400 per ton ounce was used in calculations.

**Orleans district**

The Orleans mining district is in the vicinity of the town of Orleans and covers approximately 100 mi². The district's northeast corner overlaps the northwestern part of the study area. The Orleans district includes the Rattlesnake Creek and Hayfork terranes of the western Paleozoic and Triassic belt, as well as the western Jurassic belt.

Lode mining began in the Orleans area in the 1870's and has been the primary mining activity. The Orleans bar deposit, outside the study area, has been essentially mined out. The Whitehorse, Chilton, and Whitmore Creek mines, all lode deposits, lie within the study area in the Orleans district (fig. 3). The only recorded mineral production from within the study area is 100 oz of gold and 30 oz of silver from the Chilton mine, located in metasedimentary rocks of the Hayfork terrane.

Lode gold in the Orleans district part of the study area is in quartz veins as "free gold" and is associated with pyrite. These veins strike northeast or northwest and occur in metavolcanic and metasedimentary rocks of the Hayfork terrane. Veins at the Whitehorse and Whitmore Creek mines are probably associated with the Orleans fault (fig. 2).
At the Whitehorse, Chilton, and Whitmore Creek mines, there are a total of 49,000 tons of indicated and inferred resources with grades ranging from 0.06 to 0.62 oz of gold per ton.

Red Cap district

The Red Cap mining district is centered around Red Cap Creek and covers approximately 50 mi². The southern part of the district overlaps a small part of the study area in the vicinity of the Middle Fork of Red Cap Creek, where the Hayfork terrane is present.

 placer mining in the Red Cap district began in the late 1870s along Red Cap Creek near its confluence with the Klamath River. Copper, chromium, gold, and silver lodes also occur in the district outside the study area. Within the study area, gold and silver occur in quartz veins at the Red Cap Central mine (fig. 3). Although underground exploration has been conducted at this property, located in the Hayfork terrane (fig. 3), no production was recorded. The property contains 13,000 tons of inferred marginal reserves with a weighted average gold value of 0.25 oz per ton.

ASSESSMENT OF MINERAL RESOURCE POTENTIAL

The Orleans Mountain Roadless Area has a low to high mineral resource potential for placer and lode gold. This conclusion is based on a study of known mines, prospects, and mineralized areas (Linne' and Barnes, 1982) and is supported by results of geochemical sampling (D. Smith, unpub. data, 1982). Table 2 summarizes data regarding known mines, prospects, and mineralized areas with mineral resource potential.

Gold occurs in bench placer deposits along the Salmon River adjacent to the east boundary of the study area (fig. 3). Three placer mines are present, all of which are considered to have low mineral resource potential. Resource estimates are given in table 1.

Resources of lode gold are present at mines in the northwestern and southwestern parts of the study area (fig. 3). Gold occurs in quartz veins which crosscut metasedimentary and metavolcanic rocks. Limited amounts of silver also occur at two mines. Four mines are considered to have a high mineral resource potential for lode gold; table 1 lists resource estimates for these properties.

Table 2.—Mines, prospects, and mineralized areas

[Indicated—material whose quality and quantity have been estimated partly from sample analyses and measurements and partly from reasonable geologic projections. Inferred—material in unexplored but identified deposits whose quality and size have been estimated on the basis of geologic evidence and projection. Subeconomic—known deposits not now economically minable. Marginal—the portion of subeconomic resources which would require a substantially higher price (more than 1.5 times the price at the time of determination) or a major cost-reducing advance in technology to become economic. Reserve—that portion of the identified resource from which a usable mineral or energy commodity can be economically and legally extracted at the time of determination. Names underlined are properties with mineral resources or potential; those not underlined have no potential or are poorly exposed and a determination cannot be made. A gold price of $400 per troy ounce was used in calculating the value of placer samples.]

<td>Property contains 13,000 tons of inferred marginal reserves with a weighted average gold value of 0.26 oz per ton. Assays from eleven chip samples of vein, veinlets, and country rock ranged from a trace to 0.76 oz gold per ton, and from less than 0.2 to 2 oz silver per ton. The property has a high potential for additional resources.</td>

<td>Bloomer placer mine (gold)</td>
<td>Three bench placers at 50, 200, and 400 ft above river. 15-ft-thick bench placer at 200 ft underlies 32 acres. Remnants of bench placers are at 50 and 400 ft but are not resources.</td>
<td>14 acres worked by hydraulic giants</td>
<td>10,000 oz gold; 6,000 oz silver</td>
<td>71,000 yd³ of indicated subeconomic and 642,000 yd³ of inferred subeconomic resources are estimated. Only 190,000 yd³ of inferred subeconomic resources are within the study area. Highest assay gold value from eighteen samples at six sites was $2.49 per yd³. Weighted average values for gold at each site range between $0.51 and $1.22 per yd³ with an average of $1.00 per yd³. Because of low gold values and thick overburden, this property has a moderate resource development potential. The property has a low potential for additional resources.</td>
</tr>
<tr>
<td>15</td>
<td>Potluck placer mine (gold)</td>
<td>From 10- to 20- ft-thick bench placer, 15 ft above river. Deposit occupies 71 acres.</td>
<td>5 acres worked in past Present operation is exploration and assessment work</td>
<td>700 oz gold, 100 oz silver</td>
<td>500,000 yd³ of indicated subeconomic resources and 1.5 million yd³ of inferred subeconomic resources have been identified. Only 700,000 yd³ of inferred subeconomic resources are within the study area. Weighted average value for gold at the deposit is $2.37 per yd³. Highest assay gold value from eleven samples at three sites was $5.12 per yd³.</td>
</tr>
<tr>
<td>16</td>
<td>Horn placer mine (gold)</td>
<td>Three bench placers: one 8 ft thick and 30 ft above the river; another bench which varies between 10 and 25 ft thick is 70 ft above the river; third 110 ft above the river is mined out. Gravel underlies 25 acres.</td>
<td>20 acres worked in past. No facilities or activity at present</td>
<td>125 oz gold, 100 oz silver</td>
<td>An estimated 200,000 yd³ of indicated reserves, 44,000 yd³ of inferred reserves with average value $4.97 per yd³, and 300,000 yd³ of indicated subeconomic resources with average value $0.93 per yd³ are on the property. 40,000 yd³ of indicated reserves and 20,000 yd³ of indicated subeconomic resources are within the study area. Twenty-one samples were taken from six sites. One gold nugget weighing 134 mg was found in a 1-ft channel sample. Weighted average values for gold at sample sites ranged from $0.27 to $10.59 per yd³. Because of lack of overburden and localization of values this property has a very high potential. Potential is low for additional resources.</td>

Figure 1.—Location of the Orleans Mountain Roadless Area, Siskiyou and Humboldt Counties, Calif.
EXPLANATION

- Qa: Quaternary alluvium
- Td: Tertiary (?) dikes
- Jg: Jurassic Galice Formation
- Jil: Jurassic intrusive rocks
- qd: Jurassic and (or) older quartz diorite
- msv: Jurassic and (or) older metasedimentary and metavolcaniclastic rocks (Hayfork terrane)
- mu: Jurassic and (or) older serpentinite-matrix melange, undivided (Rattlesnake Creek terrane)

Figure 2.—Generalized geologic map of the Orleans Mountain Roadless Area and vicinity (after Donato and others, 1983).
Figure 3.—Mineral resource potential and mines and prospects of the Orleans Mountain Roadless Area and vicinity.
