1 Description, composition, and tenor of unconsolidated sediments  
2 in monazite-bearing tributaries to the Savannah and Saluda  
3 Rivers in the western Piedmont of South Carolina

4 by

5- Dabney W. Caldwell

6 Introduction

7  
8 The accompanying 15 tables were prepared during 1953-54 to assist  
9 in the appraisal of fluviatile monazite placers in the basins of the  
10 Savannah and Saluda Rivers, South Carolina. Principal results ~~are~~

11 ~~are summarized in the following summary table:~~  
12 ~~Summary table~~ *have been summarized*  
13 (Overstreet, Theobald, and Whitlow, 1959, p. 709-714). Details of  
14 exploratory drilling of two monazite placers in this area were  
15 released in 1955 (Hansen and Caldwell, 1955, p. 3-25).

16 The samples described were panned by the writer, assisted by  
17 Billy R. Long, between April and November 1952. Methods used to  
18 collect the samples and pan the concentrates have been described in  
19 detail by P. K. Theobald, Jr. (1957, p. 3-6).

OPEN FILE REPORT

This map or illustration is preliminary  
and has not been edited or reviewed for  
conformity with Geological Survey  
standards or nomenclature.

U. S. GOVERNMENT PRINTING OFFICE: 1959 O - 511171

*WES*  
*(checked by WWS)*  
*(Corrected)*

1 The mineralogical analyses recorded in the tables were made in  
2 1952-53 by M. N. Girhard, H. B. Groom, Jr., R. P. Marquiss, C. J.  
3 Spengler, Jerome Stone, and E. J. Young in the laboratories of the  
4 U.S. Geological Survey. Methods used to prepare the concentrates,  
5 identify the minerals, and transpose expressions of abundance from  
6 percentage by numerical frequency to percentage by weight of the  
7 concentrate have been ~~summarized by Overstreet, Theobald, Whitlow, and~~ wms  
8 ~~Stone (1956, p. 692-694).~~ summarized by Overstreet, Theobald, Whitlow, and  
9 Stone (1956, p. 692-694). Aspects of new methods of sample splitting  
10 evolved during the work were discussed by Richard Kellagher (1953).  
11 A nomogram devised to obtain percent composition by weight from the  
12 grain counts of minerals was reviewed by R. M. Berman (1953, p. 120-  
13 123).

14 The field and laboratory work was sponsored by the Division of  
15 Raw Materials of the U.S. Atomic Energy Commission.

1 Samples from the drainage basin of the Saluda River are described  
2 in 9 tables numbered and named:

3 7. Descriptions of sediments sampled along Rabon Creek, Green-  
4 ville County and Laurens County, S. C.

5- 8. Descriptions of sediments sampled along Walnut Creek and other  
6 tributaries to the Reedy River, Laurens County, S. C.

7 9. Descriptions of sediments sampled along Horse Creek and other  
8 tributaries to the Reedy River, Greenville and Laurens Counties, S. C.

9 10. Descriptions of sediments sampled along Huff Creek and other  
10- tributaries to the Reedy River, Greenville County, S. C.

11 11. Descriptions of sediments sampled along Laurel Creek and other  
12 tributaries to the Reedy River, Greenville County, S. C.

13 12. Descriptions of sediments sampled along Turkey Creek and other  
14 tributaries to the Saluda River, Anderson, Greenwood, Abbeville, and  
15- Laurens Counties, S. C.

16 13. Descriptions of sediments sampled along Broad Mouth Creek and  
17 other tributaries to the Saluda River, Anderson, Greenville, Abbeville,  
18 and Laurens Counties, S. C.

19 14. Descriptions of sediments sampled along Grove Creek and other  
20- tributaries to the Saluda River, Anderson and Greenville Counties, S. C.

21 15. Descriptions of sediments sampled along Big Brushy Creek and  
22 other tributaries to the Saluda River, Anderson County and Greenville  
23 County, S. C.  
24  
25-

1 The location of the area to which each table refers is shown on  
2 the index to maps used for placer appraisal between the Savannah and  
3 Catawba Rivers, South Carolina and North Carolina (fig. 1). ~~\_\_\_\_\_~~

Savannah River-Catawba River district, South Carolina and North  
Carolina.

1 Description of the tables

2 A standard form has been prepared and followed to give a system-  
3 atic presentation of field and laboratory data about the samples. The  
4 form has seven main headings with a number of subheadings. Main  
5- headings are, from left to right:

- 6 1. Block
- 7 2. Station number
- 8 3. Sample number
- 9 4. Material sampled
- 10- 5. Depth of sample below surface of flood plain
- 11 6. Screening characteristics
- 12 7. Minerals in concentrate

13 Under these headings the sample is located, the collector is  
14 identified, class of sediment and dominant components described,  
15- weight of the concentrate panned from the sample is noted, and the  
16 sizes and abundances of the constituent minerals of the concentrate  
17 are given.

restraint*

Block, station number, and depth of sample below surface of  
flood plain

The block and station number identify the location of each sample

Blocks are identified by  
letter and stations by number which do not repeat in a given map area.

"Depth of sample below the surface of flood plain (feet)" is the  
measure of the vertical position of a sample below the top of the flood  
plain. For riffle samples it is the measure of the vertical height of  
the banks of the present channel of the stream.

#### Sample numbers

Sample numbers follow the system: (1) the calendar year in which  
the sample was collected is shown by the left-hand digits, (2) the  
collector is indicated by the pair of letters, (3) the samples progress  
in numerical sequence throughout the year, and (4) the right-hand  
digits show the position of a sample in the sequence collected in a  
given year by an individual. Thus, sample number 52-DC-346 was  
collected in 1952 by D. W. Caldwell, and it is the 346th sample taken  
by him that year.

5

1 Material sampled

2 The column headed "Material sampled" contains entries which give  
3 a summary of the position and grade size of the sediment sampled.

4 Position is designated as "riffle," "bank," or "terrace"  
5 accordingly as the sample was taken from the bed of the present  
6 channel of the stream, from a bank of the present channel, or from  
7 terrace deposits of an older fluvial deposition than the "bank" and  
8 "riffle" sediments.

9 Grade size of the unconsolidated sedimentary material sampled was  
10 classed as gravel, sand, silt, or clay according to field criteria.

11 Clay and silt were identified by the feel and cohesiveness of the sedi-  
12 mentary material. Alluvium was described as clay if it was unctuous or  
13 its matrix was both unctuous and the dominant component, and if it was  
14 sufficiently tenaceous to roll into rods between one's hands. Fine-  
15 grained sediments that were incapable of being rolled into rods were  
16 called silt. Various uncohesive, gritty, fine- to coarse-grained  
17 sediments were called sand or gravel depending upon the part of the  
18 material from the original volume (0.34 cu. ft.) that passed through  
19 the sieve and was caught in a pan after washing and screening the  
20 sample through a 1/8-inch sieve. In two-component mixtures of sand and  
21 gravel the sediment was called sand if 0.18 cubic foot or more material  
22 passed through the sieve, and it was called gravel if less passed  
23 through. Three- or four-component mixtures were classed as gravel or  
24 sand accordingly as the dominant constituent was retained on the sieve  
25 or caught in a pan below the sieve.

1            Estimates of the percentages of the different detrital components  
2 coarser than 1/8 inch were made to determine variations in the gross  
3 character and degree of weathering of the bedrock in the drainage  
4 basin. A dominance of quartz and potassium feldspar over rock  
5- fragments indicates lack of exposures of unweathered rock in the  
6 drainage basin. The "Maximum intermediate dimension (inches)" gives  
7 the length of the intermediate dimension of the largest fragment in  
8 the sample of alluvium.

1 Minerals in concentrate

2 The columns under "Minerals in concentrate" show the weight of  
3 the concentrate in grams, the "Sieve fraction," seven minerals of  
4 possible economic interest, seven accessory minerals, and a column for  
5- other minerals. Weight of the concentrate shows the amount of  
6 minerals panned from a sample of standard size (0.34 cu. ft.). Under  
7 "Sieve fraction" the size distribution of the minerals in the concen-  
8 trate is shown by weight percentage retained on the 45, 100, and 170  
9 mesh sieves. Where the percentage of the concentrate caught on the  
10- 32 mesh sieve or passing through the 170 mesh sieve is greater than  
11 1 percent it is also recorded.

17  
18  
19  
20-  
21  
22  
23  
24  
25-

1 The seven minerals of possible economic importance are monazite,  
 2 ilmenite, rutile, zircon, garnet, kyanite, and sillimanite. Abundance  
 3 of each of these minerals in the panned concentrate is shown as a  
 4 weight percentage of the concentrate. Dashes are used in the columns  
 5 headed "Percent of concentrate" to show that the mineral was looked  
 6 for but not found. Trace means that the mineral is present but makes  
 7 up less than 1 percent of the weight of the concentrate. The tenors  
 8 of these possibly economic minerals are given as pounds per cubic yard  
 9 of sediment in place. Tenors estimated to be less than 0.1 pound per  
 10 cubic yard are recorded to show the sparseness of the mineral, but the  
 11 estimates of less than 0.1 pound are not reliable. Tenors have been  
 12 adjusted for swell to reduce the measured volume of the sample to  
 13 approximate volume in place. For reduction of swell the factors  
 14 published by Peele and Church (1941, v. 1, p. 3-03) were used:

15-	Class of alluvium	Swell (in percent)
16	Riffle sand and gravel	14
17	Bank silt, sand, and loose gravel	20
18	Clay and compact bank gravel	35
19		
20-		
21		
22		
23		
24		
25-		

1           No adjustment for recovery in panning was applied to the  
2 estimated tenors of the samples, because the recovery is different for  
3 different minerals in the different classes of sedimentary materials.  
4 Recoveries of monazite, the mineral with which the work is concerned,  
5 were about 84 percent in the different materials, and the recoveries  
6 of the other minerals ranged from about 40 to 90 percent with the  
7 lowest recoveries being for minerals in samples of silt and clay  
8 (Theobald, 1957, p. 11).

9           The abundance of the accessory minerals of no economic value are  
10 shown as weight percentage of the concentrate. Estimates of tenors  
11 have not been prepared. Staurolite is here classed as an accessory  
12 instead of an economic mineral because of its general sparseness in  
13 the high-grade metamorphic rocks on which the fluvial placers are  
14 developed.

15           "Others" lists minor accessory minerals of infrequent occurrence.  
16 The name of the minor mineral is written above percentages showing  
17 its abundance in the concentrate. Abbreviations of the names of the  
18 minerals were given above.
