TABLES — Continued

INTRODUCTION

In graphic form, this report describes drill cores from five wells in the Lost Soldier oil field, south-central Wyoming (fig. 1). The wells are on the southwest and northeast flanks of the Lost Soldier anticline. Rocks described range in age from Permian to Precambrian, but most belong to the Tensleep Sandstone of Pennsylvanian age. Table 1 summarizes the well locations, units described, and depths of intervals cored and lists individuals responsible for the descriptions and interpretations. The report is the first of a series that will describe cores from selected wells in the Lost Soldier, Wertz, Sand Draw, Happy Springs, and Crooks Gap oil fields, Wyoming. The text and graphic descriptions have been prepared for open-file release by Mitchell W. Reynolds.

Drill cores described here were provided by Pasco, Inc., Englewood, Colorado, as part of a cooperative program with the U.S. Geological Survey, to study in detail reservoir characteristics in selected producing oil fields of central Wyoming. Careful identification of rock types and successions, stratification types, fractures, mineral cementation, and distribution of oil might aid in predicting kinds, routes, and controls of fluid migration, thereby increasing the efficiency of secondary and tertiary recovery of oil.

Acknowledgments. Pasco, Inc., provided the drill core and financed its slabbing. Thomas F. Manera, Donald R. Holbert, and Ronald G. Brown of Pasco, Inc., contributed mechanical logs and some core analyses

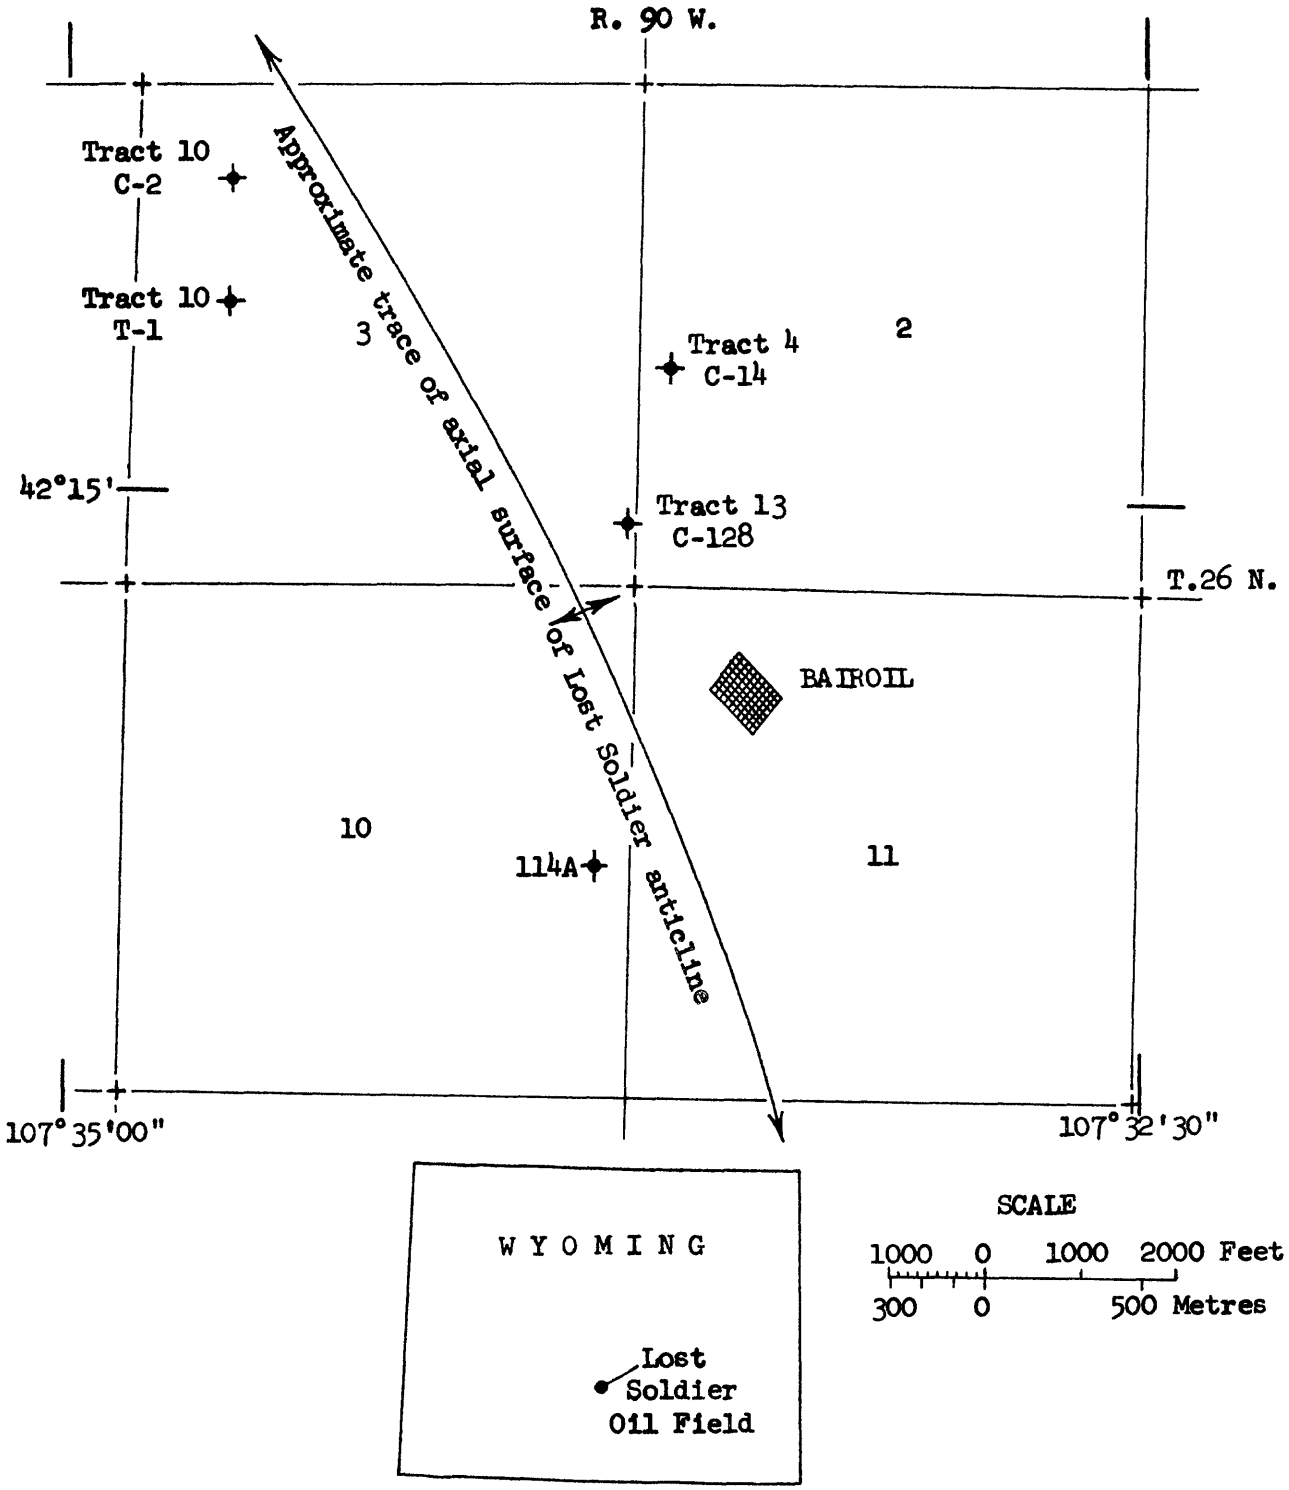

FIGURE 1. – Index map showing location of the Lost Soldier oil field and wells from which drill core is described in this report. Sections 2, 3, 10, and 11, T. 26 N., R. 90 W., are in Sweetwater County, Wyoming.

TABLE 1.--Location of wells from which cores are described in this report, showing formations with ages, depths of cored intervals, and investigators. All wells are in Sweetwater County, Wyoming.

to the study. C. Keith Fisher, U.S. Geological Survey, facilitated the handling of the core at the U.S. Geological Survey Core Library at Golden, Colorado, where William S. Bruggemeyer and Fred R. Clark transported, arranged, and catalogued the core. Cores described here are available for inspection upon request in advance at the U.S. Geological Survey Core Library, 418 Orchard Street, Golden, Colorado, 80401.

METHODS OF STUDY

Drill core examined for this report was slabbed parallel to its long axis but off-center, to produce slabs about 7.5 (3 in.) wide. Most core was not continuous because it had previously been broken and segments had been removed for core analyses, leaving segments 5-25 cm (2-10 in.) long for the present study. Each segment of slabbed core was inferred to be representative of a full 30-cm (1-ft) interval shown on figures 2 and 4-6. Only for the Atlantic Richfield Company well, Tract 13, C-128 was core continuous (fig. 3).

Table 2 summarizes abbreviations used in the graphic descriptions. The abbreviations generally follow those compiled by the A.A.P.G. Committee on Stratigraphic Correlations, as presented by Maher (1964). Tables 3-13 summarize symbols and standards used on the graphic logs and are arranged in their order of occurrence on log headings. Depths shown on the logs are in feet, as generally used by the petroleum industry in the United States. The scale along the edge of the lefthand column is in metres.

Pages of descriptions can be assembled in succession to form con-

tinuous strip logs of the intervals cored.

Examination Procedure. All slabbed core was examined under binocular microscope at magnifications ranging from about 10x to 400x. Spot chemical tests were first made on the slabbed core, then the flat surfaces were moistened with water to increase contrasts and to improve visibility of constituents for microscopic examination. Properties were identified by comparison to published standards (tables 8, 11, 12) or to standards established for this study (tables 3-7, 9, 10). Grain-size and porosity estimates were made through the binocular microscope by comparison to commercially available standards.

Identification of mineral grains and cement types was made visually through the microscope or by using mechanical or chemical tests. To distinguish calcite from dolomite, 0.1 N hydrochloric acid, calibrated first for reaction on carbonate rocks of known composition, was applied to the rock surface. Estimates of the kind and quantity of carbonate cement present were made by judging the relative speed and vigor of effervescence of the minerals in the dilute acid. Color identifications were made by comparison to the "Rock-Color Chart," published by the Geological Society of America (1963).

To test for the presence of oil where saturation was not evident, rock chips were placed in 111-trichloroethane solvent. After standing briefly, the solution was examined under long- and short-wave ultraviolet light for the intensity or absence of fluorescence resulting from the presence or absence of oil. Table 3 shows the symbols used in the graphic descriptions for estimates of different quantities of

oil saturation.

SUPPLEMENTARY DATA

Mechanical and geophysical logs, including induction electrical and laterologs, sonic, gamma ray-neutron, and caliper, were available for the wells described here. However, core depths have not been adjusted to match depths on the logs. Results of core analyses were available for some wells, and this information was incorporated graphically (tables 3 and 5) on the descriptions in the columns for oil shows and porosity (figs. 2-6).

LIMITATIONS OF THE STUDY

Study of the cores described here has been limited to visual inspection under binocular microscope. No thin sections were prepared to confirm identification of clasts, mineral cements, or fabrics; and no X-radiographs or X-ray analyses were made to study sedimentary structures or clay minerals. Because most cores were not continuous, the stratigraphic record of some breaks in sedimentation may not have been preserved.

Directional surveys for the drill holes were not incorporated into the present data. If a hole deviates significantly from a vertical orientation, values for the dip of stratification, cross stratification, or fractures measured on slabbed core may not be true values. Dips recorded on the logs were measured from an imaginary line perpendicular to the core edge; that imaginary line is assumed to be hori-

zontal. From drill-hole-direction information for several wells, we established that dips of algal laminae observed and measured on slabbed core approximate the structural dip in a hole within 4 to 10 degrees. Orientations of the cores either were not recorded at the drill site or were not marked on the cores, and so directions of dip of strata or cross-strata and fractures, or strikes of these elements are generally unresolved.

Visual estimation of porosity is difficult, and estimates differ among observers. Application of the quantitative classification for porosity shown on table 5 to the core descriptions of figures 2-6 is somewhat unequal and is approximate.

Depositional environments were interpreted from rock types, bedding and sedimentary structures, stratification sequences, and, rarely, fossils observed. The general absence of faunal control in the rocks precludes precise correlation of inferred depositional sequences, but approximate correlation of some characteristic sequences is possible. Investigators together examined some cores (wells Tract 4, C-14; Tract 10, T-1; and part of 114A) after describing them to standardize interpretations of depositional environments. Nevertheless, differences of interpretation persist for some intervals.

TABLE 10. – Symbols and abbreviations for biologic constituents observed in drill cores. (Compiled for this study by scientists of the U.S. Geological Survey)

	Algae, framework (green and red)
	Algae, nonframework (blue-green)
	Belemnite
	Bone and teeth
	Brachiopod
	Bryozoa
	Cephalopod (ammonite, nautiloid)
	Charophyte
	Conodont
	Coral
	Crinoid or Blastoid
	Decapod Crustacean
	Echinoid, stelleroid, or asteroid
	Foraminifera
	Gastropod
	Insect
	Ostracode
	Pelecypod
	Plant remains
	Scaphopod
	Sponge spicules
	Spores and pollen
	Stromatoporoid
	Tracks, type unspecified
	Trails, type unspecified
	Trilobite
	Worm tube, calcareous

TABLE 10. – Symbols and abbreviations for biologic constituents observed in drill cores.– Continued

SYMBOLS FOR SELECTED TRACE FOSSILS

Ophiomorpha

Thalassinoides

Arenicolites

Diplocraterion and Rhizocorallium

Chondrites

Asterosoma, form rod-shaped burrows

Siphonites

Teichichnus

Arthrophycus

Asterosoma, form helicoid funnel

Nondescript horizontal tracks, trails, and burrows

Nondescript vertical burrows

Zoophycus

TABLE 10. — Symbols and abbreviations for biologic constituents observed in drill cores. — Continued

(Terminology from Scott, 1970)

PRESERVATION

OR	Original material
RE	Replaced or recrystallized material

DISPERSION

U	Uniform
R	Random
C	Clumped

DENSITY

FD	Few -- less than 10 percent fossils per unit area
SD	Some -- 10-50 percent fossils per unit area
MD	Many -- more than 50 percent fossils per unit area

ORIENTATION

Long axis of fossil or commissural plane of fossil

Pl	Parallel to bedding	CU	Convex up
Pd	Perpendicular to bedding	CD	Convex down
Ob	Oblique to bedding		

DISSOCIATION OF HARD PARTS

A%	Percent articulated
D%	Percent disarticulated
L%	Percent left valve
R%	Percent right valve

FRAGMENTATION OF REMAINS

MF	Many -- greater than 30 percent broken fragments
SF	Some -- less than 30 percent broken fragments

SIZE SORTING OF ABUNDANT SPECIES

WS	Well sorted -- equal-sized specimens of each species
MS	Moderately sorted -- some specimens of different sizes
PS	Poorly sorted -- wide range in size of specimens

FAUNAL COMPOSITION

HM	Homogeneous -- species preserved together preferring same habitat
HT	Heterogeneous -- species preserved together and suggestive of different habitat

MODE OF ORIGIN

IP	In-place assemblage
DN	Disturbed-neighborhood assemblage
T	Transported assemblage
	Mixed (prefix above categories with "M" if faunal composition is heterogeneous

TABLE 10. – Symbols and abbreviations for biologic constituents observed in drill cores – Continued

ABBREVIATIONS FOR PRESERVATION AND ORIENTATION OF FOSSILS

(From Fox, 1971, p. 155)

ABBREVIATIONS

A	articulated valves
BR	branching
C	contact between fossil and matrix
CA	calcite
CL	closed valves
D	disarticulated valves
FR	fragmented
I	inner surface of shell
L	lift valve
M	external mold
O	outer surface of shell
OP	open valves
OR	original material
R	right valve
RE	replaced or recrystallized shell material
S	sediment fill
ST	stacked shells
ni	no information
rand	random
clump	clumped

EXAMPLE OF USE

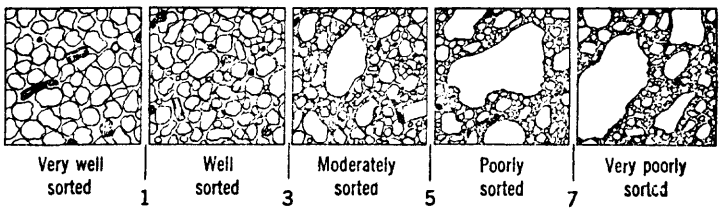
Faunal element	Preservation
Corbula sp.	CL-A; OR; I-C-S

Interpretation: Corbula sp. shells are closed, articulated, and composed of original shell material; the inner surface of the shell is in contact with a matrix of sediment.

TABLE 11. – Charts for estimating degrees of sorting as seen in two dimensions and degrees of roundness of detrital grains (From Compton, 1962, p. 214-215)

DEGREES OF SORTING AS SEEN IN TWO DIMENSIONS

Abbreviations on core descriptions vw w m p vp



Terms for degrees of sorting. The numbers indicate the number of size-classes included by the great bulk (80 percent) of the material. The drawings represent sandstones as seen with a hand lens. Silt and clay-size materials are shown diagrammatically by the fine stipple.

DEGREES OF ROUNDNESS OF DETRITAL GRAINS

Abbreviations on core Descriptions v ang ang sbang sbrd rd w rd

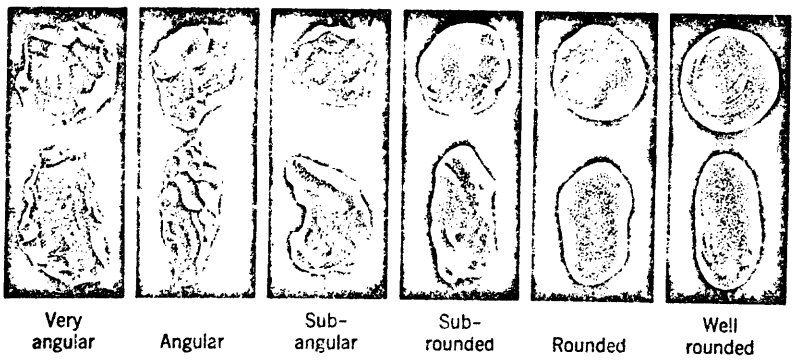


TABLE 12. – Chart for visual estimation of percentage composition (Prepared by R. D. Terry and G. V. Chilingar, 1955, Jour. Sed. Petrology, v. 25, no. 3, p. 229-234, and reproduced here from Compton, 1962. p. 332-333.)

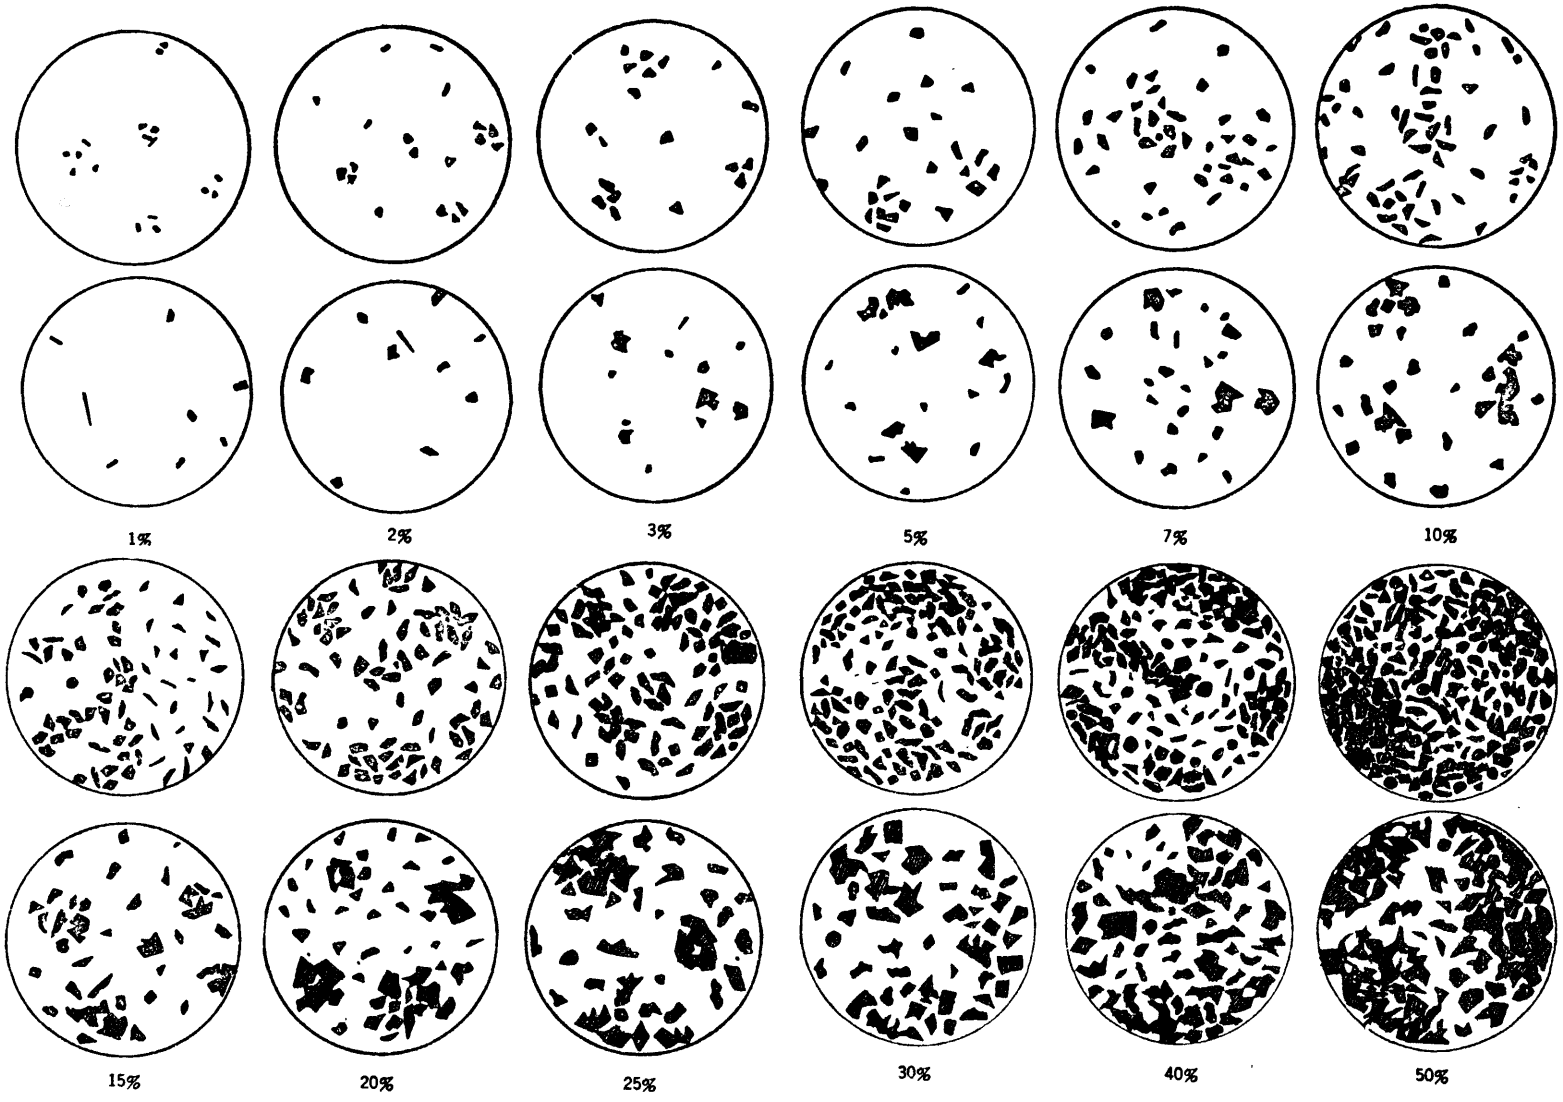

TABLE 13. – Nomenclature used for inferred environments of deposition of terrigenous clastic sedimentary rocks described from drill cores in this report
