PRELIMINARY GEOLOGIC MAP OF THE SOUTHEASTERN REGION  
YEMEN ARAB REPUBLIC, LANDSAT-1 IMAGE NO. 1206-06504

By

M. J. Grolier and W. C. Overstreet

U. S. Geological Survey

76-745

This report is preliminary and  
has not been edited or reviewed for  
conformity with Geological Survey  
standards or nomenclature

The project report series presents information resulting from  
various kinds of scientific, technical, or administrative studies.  
Reports may be preliminary in scope, provide interim results in  
advance of publication, or may be final documents.

# PRELIMINARY GEOLOGIC MAPS OF THE

## YEMEN ARAB REPUBLIC

By

M. J. Grolier, and W. C. Overstreet  
U. S. Geological Survey

### INTRODUCTION

#### Objectives of the project and scope of the mapping

This is one of nine separate preliminary geologic maps at 1:500,000 scale covering the entire Yemen Arab Republic (YAR). Each of the nine maps corresponds to an area of the Yemen Arab Republic covered by a Landsat (formerly ERTS) image. The respective Landsat images were used as the bases on which each of the maps was compiled, after stratigraphic and structural analysis in the office, and subsequent checking in the field. This work, in 1975, is one of the services called for under PASA ASIA (IC) YEM-925-22-74 between the U. S. Agency for International Development (USAID) and the U. S. Geological Survey (USGS) for a water and mineral survey in the Yemen Arab Republic, to be performed in cooperation with the Central Planning Organization, the Ministries of Agriculture and Economy, and the Mineral and Petroleum Authority of that country. Part of the program called for a Landsat survey of the country, and one of the goals of the sub-project was to produce a Landsat mosaic of the Yemen Arab Republic.

A substantial part of the imagery used in this study was provided by the National Aeronautics and Space Administration (NASA), Goddard Space Flight Center, under a Memorandum of Understanding between the USGS and NASA.

The intent in compiling these geologic maps was to bring together, at a convenient working scale, previously known and recently acquired geologic data. It is hoped that this set of maps can be used as a tool in hydrologic investigations, minerals exploration, in regional planning, economic and industrial development, highway engineering, and, also, as an aid in mapping the regional geology of the YAR at a larger scale, such as at the 1:100,000 scale.

Permission to release these geologic maps to the open file of the U. S. Geological Survey was given on March 2, 1976, by Dr. A. A. El-Eryani, Minister of Development, and Chairman of the Central Planning Organization, Yemen Arab Republic. The maps are being released in this limited preliminary version, prior to formal publication on a Landsat base. A geologic explanation on a separate sheet accompanies each of the nine geologic maps.

#### Reconnaissance field checking

Two field trips were made to the YAR in connection with this program. The first field trip, which included reconnaissance on the ground and from the air, was made between June 16 and July 13, 1975, jointly by Maurice J. Grolier and William C. Overstreet (USGS). During the trip it was possible to check an early version of the geologic map, to visit several mineral prospects, and to collect samples of rocks, ores, and slags. The samples were analysed in November 1975 at the laboratories of the USGS in Denver, Colorado. Description of the samples and results of the analyses were presented in a previous report (Overstreet and others, 1976). The second field trip for further checking on the ground was made by Grolier alone between February 1 and 29, 1976, in connection with a hydrologic reconnaissance of the country.

### Acknowledgments

The authors are pleased to acknowledge the courtesies and interest of the officials who made possible the work that has led to the preparation and release of this geologic map. They were His Excellency, Dr. A. A. El-Eryani, Minister of Development; Hamoud Ahmid Daif Allah, President, Mineral and Petroleum Authority, Ministry of Economy, YAR, and Aldelmo Ruiz, Director, USAID Mission to the YAR. Without their aid, this work could not have been done.

The authors also wish to acknowledge help received from G. C. Tibbitts, Jr., USGS Project Chief, Water and Minerals Survey in the YAR, who made arrangements for both field trips in June-July 1975 and February 1976, and from their associate, Mohammad Mukred Ibrahim, Assistant Chief Minerals Geologist, Mineral and Petroleum Authority, who cleared all the trips through local authorities and who was a constant source of information on the geology, ore deposits, and geography of the YAR. The writers were also fortunate to be accompanied on the 1975 field trips by Mohammad Luft El-Eryani, a third-year undergraduate student in geology at the College of Science, Kuwait University. His careful observations and refreshing questions added greatly to the discussions at the outcrops.

James W. Aubel, a United States Peace Corps Volunteer and geologist working with G. C. Tibbitts, Jr., on the USAID water supply project in Yemen, had discovered several fossil localities in the Amran Series. He kindly led the writers to these localities and helped in making collections of fossils. In many other ways he contributed to the field work. Help was most generously given by Roy O. Jackson, USGS, in planning the work and in interpreting the results.

Discussions in Sana'a with Dr. Joachim Thiele, Party Chief, Mission to Yemen of the Bundesanstalt für Geowissenschaften und Rohstoffe of the Federal Republic of Germany, and Dr. Karl-Heinz Schultze, Chief (in replacement of Dr. Thiele), and members of their staff, particularly Dr. Norbert W. Roland and Dr. von Prosch, were enlightening. Michael Glase, hydrologist, Tipton and Kalmbach, Inc., Denver, Colorado, and Peter S. Walczak, Resident-Oceanographer at Al Hydaydah, U.N. Food and Agricultural Organization, also supplied valuable geologic information.

Double or fractional symbols indicate grouped formations: Symbols queried where identification doubtful.

GEOLOGIC MAP SYMBOLS

Geologic names and symbols given below apply to the whole area of the Yemen Arab Republic; some names and symbols may not appear on the geologic map of an area covered by an individual LANDSAT-1 image. Names and descriptions of geologic units, unless otherwise noted, are adopted from U.S. Geological Survey and Arabian American Oil Company, 1963, Geologic map of the Arabian Peninsula; U.S. Geol. Survey Misc. Geol. Inv. Map 270-A, and Brown, G. F., and Jackson, R. O., 1959, Geology of the Asir quadrangle, Kingdom of Saudi Arabia: U.S. Geol. Survey Misc. Geol. Inv. Map 217-A.

Qsb Silt, clay, and muddy sand; commonly saturated with brine and salt encrusted; in mud flats (sabkhas) along the Red Sea coast.

Qu River terrace deposits, alluvial fans, gravel, sand, and silt including unmapped alluvium which overlies rock salt at Jabal Kusah, near Guma; numerous loess deposits particularly in the central plains. Wherever possible, alluvial deposits have been divided regionally on a basis of reflectance, natural vegetation and crops, altitude, and location into six sub-units, as follows: Qa1g, alluvial gravel, sand, and silt restricted to channels and flood plains of present-day ephemeral streams; Qa1f, alluvial gravel, sand, and silt on river terraces and fans, adjacent to and higher than the flood plains of present-day streams; generally darker than Qa1g; may include colluvium at base of foothills; Qa1d, same as above, but darker, and possibly older; Qa1c, same as Qa1g, but higher and older; Qa1b, same as Qa1g, but higher and farther inland from the Red Sea Coast; Qa1a, alluvial gravel heavily coated with desert varnish, restricted to dissected river terraces on the south valley slope of Wadi Jawf, north of Jabal Bahra and west of Wadi Raghwan.

Qk Yellow and green marly limestone, white limestone, and reef limestone, undifferentiated, exposed on Kamaran Island. Fosilliferous, and of probable Pleistocene age (MacFadyen, 1930; Cox, 1931). Probably correlative with unmapped marine terrace deposits which disconformably overlie Plio-Miocene tuffaceous sandstone at the Al Luhayyah diapirs.

Ql Loess deposits, with calcareous concretions and caliche layers; fossil mollusks abundant locally; may include alluvial silt alternating with alluvial or colluvial gravel.

Qe Eolian sand, commonly mobile.

Qa Basalt flows and dikes; numerous scattered cones and craters; at places covered with tuff and volcanic bombs. May be rock and time equivalent of the Aden Volcanic Series in the People's Democratic Republic of Yemen; in the San'a region, lava flows have been divided regionally on a basis of reflectance into four sub-units, as follows: Qa4, very dark basaltic lobate flows, extruded in historical times, possibly in 3rd century A. D. (Rathjens, G., and Wissman, H. V., 1934, v. 2, p. 13; v. 3, p. 105, fig. 51; p. 162-163; Rathjens, C., and Wissman, 1942, v. 33, p. 276); Qa3, dark basaltic flows; Qa2, thin basalt flows, discontinuous over older rocks; appear lighter gray than units Qa3 and Qa4 on LANDSAT-1 images; Qa1, basalt flows forming a continuous mantle over older rocks; Qa1 and Qa2 possible are part of only one eruption phase.

Tba BAID FORMATION--Gray, red, and green siliceous and tuffaceous shale and sandstone; also limestone and evaporite layers. Includes rock salt of salt domes at Salif and Jabal Qimnah, and at Jabal Kusah near Guma. Generally unfossiliferous, but middle to late Miocene microflora reported by Klaus (in Heybroek, 1965, p. 34-35) from rock salt at Jabal Kusah, and at Salif, and late Pliocene microfauna reported from marine sediments overlying salt (Goerlich, 1956, p. 213-214). Correlated with rocks of the Baid Formation exposed in Wadi Baid, Saudi Arabia, because of similar lithology (Gillmann, Letullier, and Renouard, 1966, p. 1479-1480, pl. 1, fig. 4).

Ta Hypabyssal andesite and diabase intrusives, commonly glomeroporphyritic, and in dike swarms.

Tgr Alkali granite and diorite in subvolcanic plugs, stocks, and plutons (Karrenberg, 1959, v. 17, no. 1, p. 33-36); leucocratic granite locally has primary flow banding. Crests of unbreached plugs may be overlain by hydrothermally altered rocks of the Yemen Volcanics, locally in northwestern part of the Yemen Arab Republic mapped as Tertiary laccoliths (U.S. Geol. Survey and Arabian American Oil Co., 1963). Some granitic plutons as at Jibal Sabir, south of Taiz, have ayenite margins. A K-Ar age of 22.7 ± 0.9 m.y. is reported for a granite sample from Jibal Sabir collected by R. O. Jackson (Field No. ROJ-1), and analysed by R. F. Marvin, H. H. Mennert, and Violet Merritt (Marvin, 1974, written commun. to G. F. Brown). A similar K-Ar age (22.0 ± 0.7 m.y.) is reported by Marvin (1974, written commun. to Brown) for a syenite sample which had been collected from a plug cutting a laterite deposit in the Sirat Plateau, Saudi Arabia by Brown (Field No. 519B).

Tl Alkali basalt flows. Erosional remnants on laterite (TI) developed over Precambrian crystalline rocks; basalt probably equivalent to As Sirat Volcanic rocks of Saudi Arabia (Coleman, and others, 1975) for which isotopic ages of 25 to 29 m.y. are reported (Brown, 1970, p. 75-87); may be equivalent to Yemen volcanics sub-unit KTY6.

TKy YEMEN VOLCANICS, undivided--Bedded alkalic flows and pyroclastic rocks including but not restricted to rhyolite, comendite, pantellerite, trachyte, andesite, basalt, and ankaramite (Shukri and Basta, 1955, v. 36, p. 129-163), with interbedded lenticles of fluviatile and lacustrine sand, clay, and shale; locally contains fresh-water Oligocene-Miocene fossils; upper surfaces of many volcanic beds weather to reddish paleosols a few centimeters to a few meters thick, particularly in middle and upper parts of the sequence; whole sequence of Yemen Volcanics at least 2,000 meters thick. Term Yemen Volcanics introduced here to replace former name Trap Series (Geukens, 1966), to emphasize presence of thick sequence of highly fractionated felsic volcanic rocks. Wherever possible, the Yemen Volcanics have been divided regionally on basis of reflectivity and stratigraphic succession into six sub-units, as follows: TKY6, dark basaltic flows; TKY5, generally leucocratic felsic tuffs with some dark basaltic flows, associated with the formation and collapse of a circular volcanic structure, 8.5 km in diameter, in the north-central part of the area covered by LANDSAT-1 image 1189-06561; TKY4, predominantly felsic and tuffaceous, with some basaltic flows, underlies TKY5 and TKY6; TKY3, predominantly felsic and tuffaceous; older than TKY4; TKY2, predominantly felsic and tuffaceous; older than TKY3; TKY1, predominantly basaltic, but includes green felsic conglomerate, porphyritic trachyte, and pink tuffs; overlies the Tawilah Group.

TKT TAWILAH GROUP AND MEDI-ZIR SERIES undivided--Continental type coarse crossbedded sandstone with lenses of conglomerate and gravel; interbedded shale and sandstone in lower part; overlies rocks of Jurassic age or the basement complex; includes the Med-zir Series, consisting of crossbedded sandstone with locally fossiliferous calcareous sandstone and shale; upper part of sandstone locally rich in hematite; the Med-zir Series cannot be separated with certainty from the Tawilah Group on basis of stratigraphic relations or reflectance.

Jam AMRAN SERIES--Limestone, marl, and shale; lower part locally includes detrital beds. The series is overlain by a less widespread Upper Jurassic transition zone of gypsum, clay, marl, shale, sandstone, and some limestone. Of Cretaceous to Kimmeridgian age. In the extreme northwestern part of the Yemen Arab Republic formerly designated the Hanifa Formation (Brown and Jackson, 1959).

Jko KOHLAN SERIES--Green shale with sandstone and conglomeratic bands in lower part; sandstone and some conglomerates in upper part. Contact with overlying Amran Series is gradational. May be in part Triassic in age; in the extreme northwestern part of the Yemen Arab Republic, formerly designated as the Khams Formation (Brown and Jackson, 1959).

OW WAJID SANDSTONE--Partly crossbedded, locally conglomeratic sandstone; includes common quartz granule and pebble zones; of Ordovician age (Brown, 1970); formerly designated as Permian or older (U.S. Geol. Survey, and Arabian American Oil Co., 1963).

BP Paralkaline granite, gneiss, and syenite, generally massive; includes some quartz in circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

SY In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR In circular plugs, stocks, and ring dikes. Calc-alkaline granite, gray and pink, generally massive; includes some quartz monzonite; may have been intruded during second and third episodes of the Hijaz tectonic cycle recognized in southwestern Saudi Arabia (Greenwood and others, 1975, p. 23).

GR Gneissic granite, gneissic granodiorite, and injection gneiss; commonly intruded by swarms of mafic dikes, contains numerous septa and inclusions of schist and gneiss; may have been intruded during second episode of Hijaz tectonic cycle.

GR Diorite, d, and gabbro, gb; may have been intruded during second episode of the Hijaz tectonic cycle.

GR Slate, pelitic schist, and quartzite, sl; chlorite-schist, graphitic schist, sc; low-grade metamorphosed sedimentary rocks possibly of second and first episodes of Hijaz tectonic cycle.

GR Marble, quartzite, and biotite gneiss, mq; biotite schist, biotite gneiss, and quartzite, bq, intruded by dikes of gneissic pink granite, diorite, and gabbro; medium- and high-grade metamorphosed sedimentary rocks possibly of second and first episodes of Hijaz tectonic cycle.

GR Mafic volcanic and metavolcanic rocks, with some interlayered metagraywacke and metaconglomerate, consisting of andesite, meta-andesite, metabasalt, greenstone, and chlorite schist, sb; hornblende gneiss, and amphibolite, am; possibly of second and first episodes of Hijaz tectonic cycle.

GR Predominantly granite, gneiss, and mica schist with subordinate quartzite, hornblende schist, and marble.

GR Chlorite-sericite schist, amphibole schist, graphite schist, marble, quartzite, slate, conglomerate, and greenstone.

GR Thaniya Group, contorted and cleaved metasediments consisting of graphitic calc-schist, quartzite, phlogopite marble, chert, and associated volcanics.

NOTE

The gossans in the Kingdom of Saudi Arabia at Wadi Wassat (Overstreet and Rossman, 1970), and at Wadi Qatan (Dodge and Rossman, 1975) were formed over extensive deposits of stratabound massive and disseminated pyrite and pyrrhotite in Precambrian volcanogenic rocks. Should the iron deposits near Sa'dah, which are known to extend tens of kilometers northward, and similar deposits gossans over massive sulfide, then the region mined for iron northward from the vicinity of Sa'dah and Majadh to the border between the Yemen Arab Republic and the Kingdom of Saudi Arabia merit geologic, geophysical, and geochemical exploration for base metals, nickel, silver, gold and molybdenum.
