Open-File Report 78-559

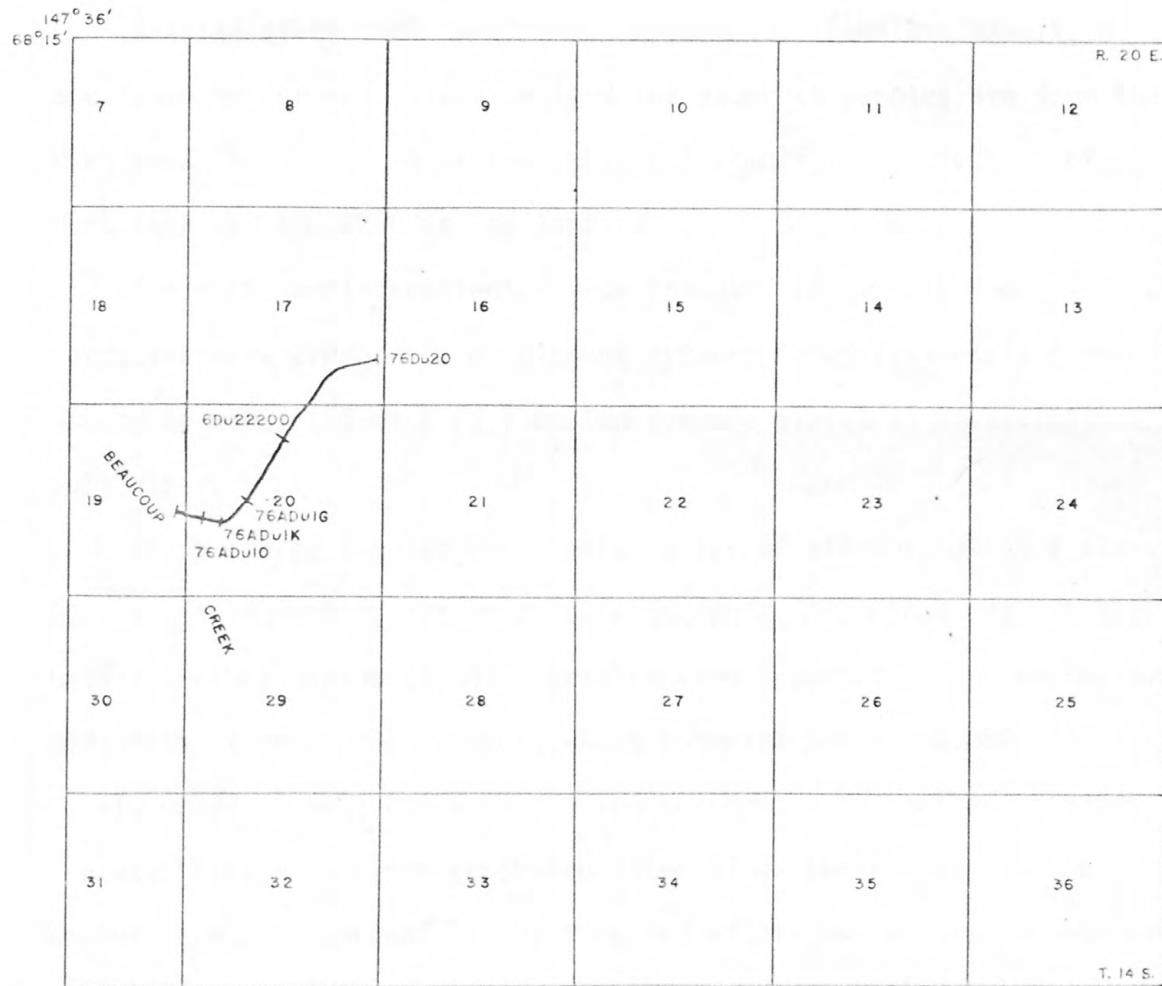

1978

More than 1400 m of fine-grained clastic rocks and reefoid limestones constitute the lower part of an Upper Devonian transgressive-regressive cycle in the central Brooks Range, Alaska (Dutro and others, 1977). The Hunt Fork Shale and an underlying heterogeneous unit (unnamed) were measured and sampled on the east side of the upper Beaucoup Creek in the Philip Smith Mountains A-1 quadrangle (secs. 17, 19, and 20, T. 14 S., R. 20 E.) (Brosgé and others, 1977).

The Hunt Fork Shale, predominantly laminated, noncalcareous dark silt-shale, includes several fine-grained sandstones intervals and a few shelly limestone beds containing Frasnian brachiopods, molluscs, and corals. The partial measured section of Hunt Fork Shale, more than 700 m thick, contains at least five minor cycles, each of which grades upward from fine-grained sandstone through silt-shale to dark gray shale or mudstone. Two of these cycles contain thin limestone beds in their upper parts.

The Hunt Fork Shale sequence was measured from the top downwards to the contact with reefoid limestone that caps the unnamed unit. Channel samples of the darker shales were collected about every 15 m for subsequent chemical analysis. In addition, three dark shale intervals in the unnamed formation were similarly sampled (Fig. 1).

Philip Smith Mountains A-1 quadrangle, Arctic Alaska

Figure 1.-- Map showing location of measured section; upper and lower sample sites of the Hunt Fort Shale, 76Du20 and 6Du22200 respectfully; and three sample sites from the underlying unnamed formation, (sections 17, 19, and 20, T. 14 S., R. 20 E.).

A total of 48 rock samples was collected. Samples 76ADu1K, G, and 0 are from the unnamed formation, and the other 45 samples are from the Hunt Fork Shale; 76Du20 is the uppermost sample in the section of the Hunt Fork and 6Du22200 is the lowest.

The rock samples collected from the Hunt Fork Shale and the unnamed formation were crushed in a chipmunk crusher to approximately 6 mm and ground to minus-150-mesh (0.1 mm) on ceramic plates in a vertical pulverizer.

The prepared samples were analyzed for 30 elements using a six-step D.C.-arc semiquantitative emission spectrographic method described by Grimes and Marranzino (1968). Results were reported as the approximate midpoints of geometric brackets whose boundaries are: 0.082, 0.121, 0.177, 0.261, 0.383, 0.562, 0.825, etc. The spectrographic method provides repeatability within one reporting interval of the reported value approximately 83 percent of the time and within two reporting intervals of the reported value approximately 96 percent of the time (Motooka and Grimes, 1976).

Atomic-absorption spectroscopy was used to determine the concentration of zinc in the prepared samples. This method provides a precision of plus or minus 1 percent of the reported value (Ward and others, 1969).

Results of the rock analyses appear in table 1. Column 1 contains the sample field number; in samples 76Du20 through 6DU22200, the digits following the suffix 76DU2 or 6DU 2 indicate the stratigraphic position in feet from which the sample was taken in the measured section of Hunt Fork Shale. Latitude and longitude are expressed in degrees. Columns in which the element heading is preceded by an S contain element concentrations determined by emission spectroscopy. Atomic-absorption results for zinc appear in the last column under the heading AA-Zn-P. Results for all elements are reported in parts per million except iron, magnesium, calcium, and titanium, which are reported in percent.

An "N" in table 1 indicates that the element was not detected, and "<" indicates that the element was detected, but that the value was below the limit of detection.

The approximate visual lower limits of determination for the 30 elements analyzed by semiquantitative emission spectrography included in this report are as follows: for those elements reported in percent--iron and calcium, 0.05; titanium, 0.002; and magnesium, 0.02; for those elements reported in ppm--silver, 0.5; beryllium, 1; cobalt, copper, molybdenum, nickel, and scandium, 5; manganese, gold, boron, bismuth, chromium, lead, tin, vanadium, yttrium, and zirconium, 10; barium, cadmium, lanthanum, and niobium, 20; tungsten, 50; antimony and strontium, 100; and arsenic and zinc, 200. The lower limit of detection for zinc by atomic absorption is 5 ppm.
