**Abstract**

Semiquantitative emission spectrographic analyses for 64 elements on 98 stream sediment and 122 rock samples from Mountain Lake Wilderness Study Area, Giles and Craig Counties, Virginia and Monroe County, West Virginia, are reported here in detail. Locations for all samples are in Universal Transverse Mercator (UTM) coordinates. Brief descriptions of rock samples are also included. Rocks analysed are mostly sandstone. Samples of hematitic sandstone of the Rose Hill Formation and limonite-cemented sandstone of the Rocky Gap Sandstone contain high values of iron; these rocks are submarginal iron resources. Some of these iron-rich samples have a little more barium, copper, cobalt, lead, silver, and/or zinc than in average sandstone, but they do not suggest the presence of economic deposits of these metals. A few samples of Tuscarora Quartzite contain moderate amounts of manganese. These are from a submarginal manganese resource. No other obviously anomalous values related to mineralized rock are present in the data.

**Introduction**

The analyses reported in this open-file report are on samples from the Mountain Lake Wilderness Study Area and vicinity, Giles and Craig Counties, Virginia, and Monroe County, West Virginia, collected by M.P. Foose, P.J. Geraci, F.G. Lesure, D.R. McQueen, P.L. Weis, and Helmuth Wedow in April 1975. The samples include 98 stream sediments from the study area and vicinity and 122 rock samples. The rock samples, which are described briefly, are for the most part chip samples of representative materials collected from outcrop or road cut. A few are composite samples of representative float material. Some of the rock is partly weathered but the freshest material available was generally sampled.

Sample locations and discussion of the results of the analytical work are given by Lesure and others (1978).

## Analytical techniques

The stream sediment samples were dried and sieved in the laboratory; the minus 80-mesh fraction was used for analyses. The rock samples were crushed and split.

The semiquantitative emission spectrographic analyses were made using computerized equipment. This method permits a rapid electronic recording on magnetic tape of the optical transmissions of all lines in a spectrogram. The tape is read by a computer which has been programmed to determine the concentrations of 64 elements. The standard deviation of any single answer should be taken as plus 50 percent and minus 33 percent. The third significant figure, when reported, appears solely for programming convenience and should not be used in publications.

All the samples were also tested for gold by a combined fire assay-atomic absorption method in the U.S. Geological Survey laboratories, Reston, Va., by Herbert Kirschenbaum and B.A. McCall. No gold was detected at a limit of detection of 0.05 parts per million (ppm) Au.

## Explanation of table

The X and Y coordinates are Universal Transverse Mercator (UTM) grid, zone 17. The X coordinate is the easting value; the Y is the northing. Symbols used include: S, semiquantitative spectrographic analysis, <, less than lower limit; >, greater than upper limit; .0 interference for an element which cannot be resolved by any routine method. The limits apply under ideal conditions, and in some cases interferences will narrow the limits. All data are in parts per million (ppm) except where indicated in percent (%). Elements looked for but not found and the lower limit of determination:
