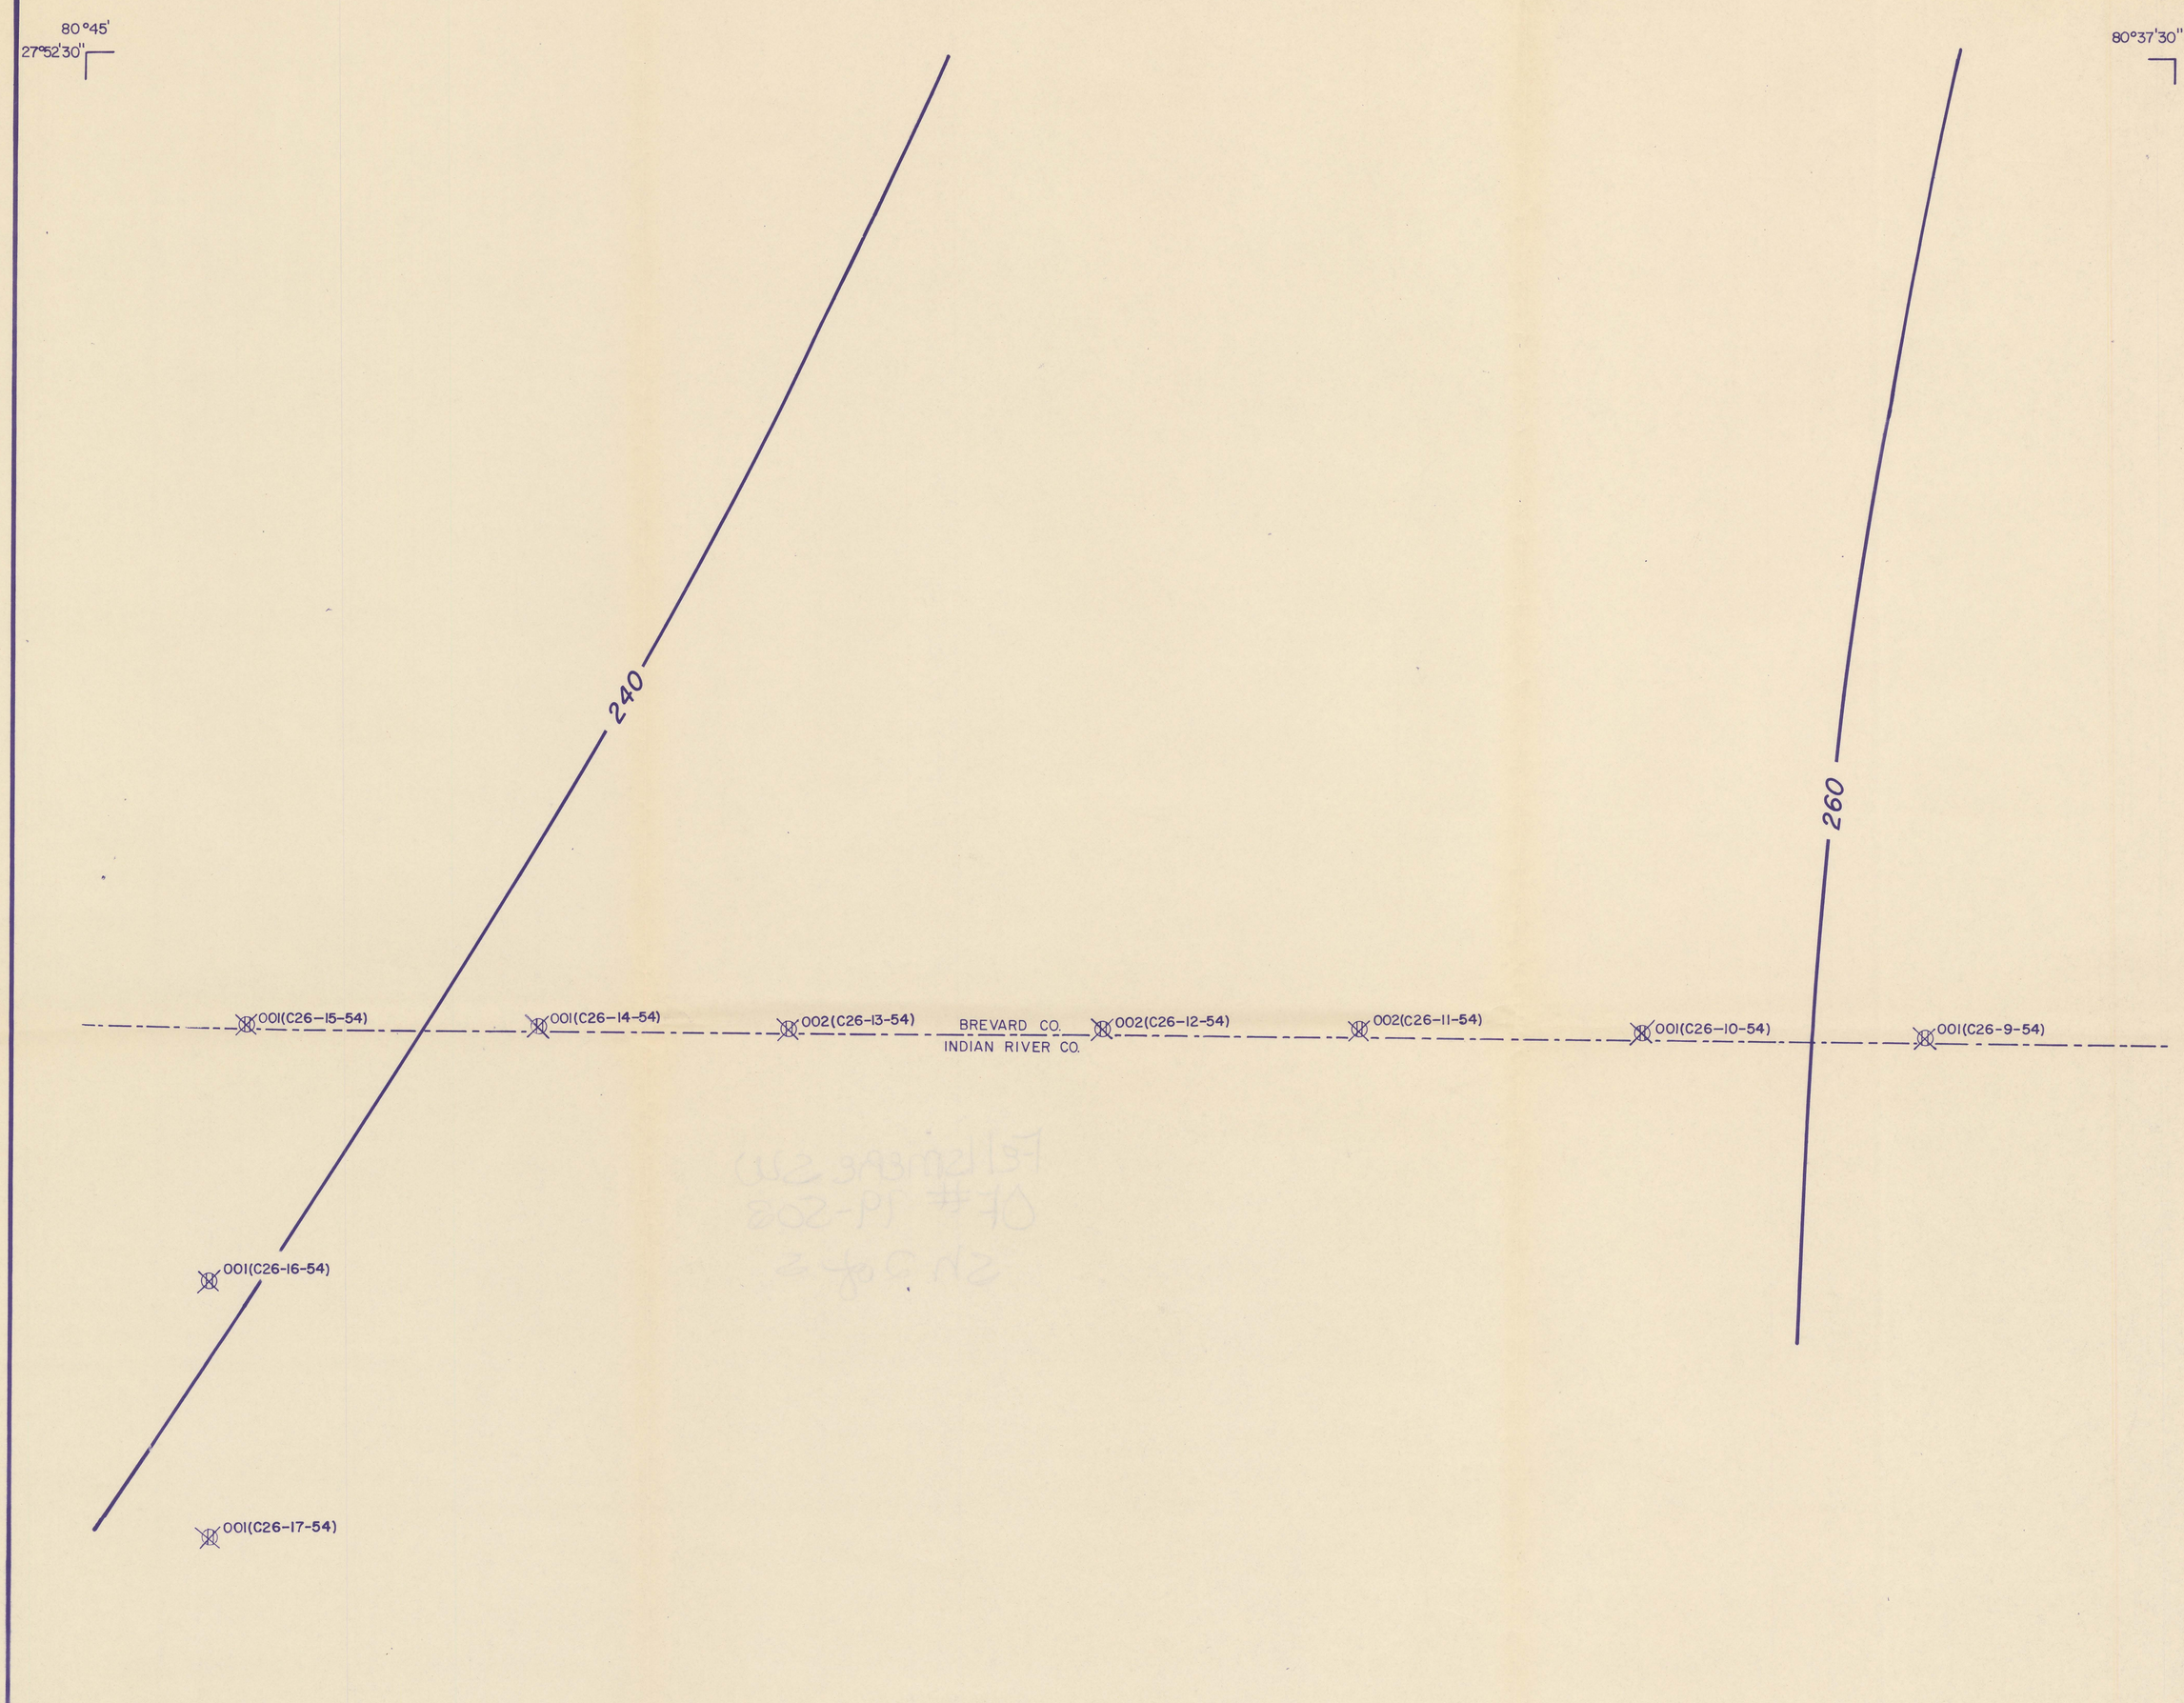
OPEN-FILE REPORT
79-503
SHEET 2 of 5



FELLSMERE SW QUADRANGLE, FLORIDA
1953, PHOTOREVISED 1970,
7.5-minute series, 1:24000

EXPLANATION

240 — Altitude of top of Floridan aquifer, in feet below mean sea level. Contour interval 20 feet.

○001(C26-17-54) Corps of Engineers test hole. Number is last three digits of local well number (sheet 1). Letter-number combination in parentheses is field or agency identifier; final two digits denote year drilled.

◍ Test hole

⊗ Destroyed

Note: The overlay shows altitude of top of Floridan aquifer and is based on the shallowest known occurrence of limestone of Eocene age. The contours were originally defined in 1953 (Neill, 1955), and refined in 1955-57 (Brown and others, 1962a) and 1974-76 (references, sheets 2 and 3).

GEOHYDROLOGY

The Brevard County portion of the Fellsmere SW quadrangle consists largely of marshlands that have been drained for agricultural purposes. Surface drainage is through the swamps and constructed drainage outlets which ultimately drain the higher areas to the St. Johns River or the Indian River estuary.

Ground water occurs under nonartesian and artesian conditions. Nonartesian conditions occur where the upper surface of the zone of saturation (water table) is free to rise and fall in direct response to local rainfall (recharge) and to discharge. Artesian conditions occur where the water in an aquifer is confined by a bed of less permeable material and will rise in a tightly cased well above the base of the confining bed. The level to which the water will rise defines the altitude of the aquifer's potentiometric surface at that location. If the potentiometric surface is above land surface, the well will flow (sheet 3). Water-level measurements in many artesian wells are used to define the configuration of the potentiometric surface over broad areas (sheet 3).

Unconsolidated sediments of Holocene, Pleistocene, and late Miocene age constitute the nonartesian (shallow) aquifer. These sediments lie above the consolidated limestone formations of Eocene age known as the Floridan aquifer. The altitude of the top of the Floridan aquifer is shown on sheet 2. The middle Miocene deposits (Hawthorn Formation) overlie and tend to confine the Floridan aquifer. Where the confining beds are discontinuous and limestones of Miocene age are present, there is usually a hydraulic connection between the middle Miocene and the Eocene deposits.

The entire quadrangle is an area of artesian flow for the Floridan aquifer (sheet 3), which contains water with chloride concentrations in excess of 300 mg/L throughout the quadrangle (sheet 4). Quality of water in the shallow aquifer is not known, as this aquifer is not utilized in the area. Ground-water use is almost entirely for agricultural purposes, and is obtained from the Floridan aquifer.

SELECTED REFERENCES

This report is 1 of 29 similar map reports prepared on the 7½-minute topographic quadrangle base to cover all of Brevard County (see index, sheet 1). A complete list of references used in preparation of the 29 reports is given below. Individual abbreviated references are noted on the various sheets, as applicable; the user may refer to the following list to obtain the formal reference.
