

POTENTIOMETRIC SURFACE OF THE FLORIDAN AQUIFER

INTRODUCTION

The configuration of the potentiometric surface of the Floridan aquifer and the water table in the surficial aquifer in parts of west-central Florida in the vicinity of well fields used for public supply are shown on sheets 1 and 2. The maps encompass land areas of about 1,200 sq mi and include parts of Hillsborough, Pinellas, Pasco, and Sarasota Counties. The maps are prepared semiannually by the U.S. Geological Survey in cooperation with the Southwest Florida Water Management District and local agencies. Water levels generally are lowest in May and highest in September. In contrast, pumping is highest in May and lowest in September. The surficial aquifer consists of unconsolidated, fine-grained sediments as much as 80 feet thick. In most areas, the surficial aquifer is underlain by clay that forms a leaky confining layer separating the surficial aquifer from the underlying limestone of the Floridan aquifer. In southern Hillsborough County and Sarasota County, confining beds separate the Floridan aquifer from overlying artesian aquifers. The Floridan aquifer consists of limestone and dolomite beds about 1,000 feet thick. Sixteen well-field areas were mapped: Brandon, Clearwater, Dunedin, Belleair, Come, Cross-Bar Ranch, Cypress Creek, East Lake, Eldridge-Wilde, Morris Bridge, Pasco, Riverview, Section 21, Starkey, Sun City, and Verna. The well fields supply water to the urban and suburban areas of Brandon, Clearwater, St. Petersburg, Sarasota, and Tampa, and Pinellas and southern Hillsborough Counties.

SUMMARY OF CONDITIONS

In May 1979, water levels in most observation wells in the surficial aquifer and the Floridan aquifer were higher than those measured in September 1978 and much higher than the average May levels. Seasonal and year-to-year fluctuations of water levels in the surficial and Floridan aquifers, and their relations at each well field are shown by hydrographs.

The May 1979 potentiometric surface of the Floridan aquifer at all well fields was generally much higher than May 1978. Increases ranged from zero at Sun City well field to about 8 feet at Eldridge-Wilde well field, and averaged about 4 feet. The water table in the surficial aquifer was 1 to 2 feet higher. Water levels in both aquifers were about 2 to 3 feet higher in May than in September 1978 in most well fields, the exceptions being Cypress Creek, Riverview, Sun City, and Verna well fields.

Rainfall in the area was below the 1941-70 normal in October and November 1978 and in February, March, and April 1979, and greater than normal in December 1978 and in January and May 1979 (table 2). There was heavy rainfall one week prior to measurements of water levels. On May 15, 1979, the total pumping from the producing wells was 127.9 Mgal, 4.2 Mgal more than that recorded on September 26, 1978, and 38.7 Mgal less than that recorded on May 16, 1978 (table 3). Most well fields pumped less water on May 15 than the previous May, excluding Cypress Creek and East Lake well fields where pumping was greater.
