

- This map has been compiled from the following sources:
1) John Decker and Susan Karl - field mapping, July, Aug., and Sept., 1977.
2) John Decker, Neil Lundberg, and Susan Karl - field mapping, May, June, July, Aug., and Sept., 1978.
3) Bruce R. Johnson, Susan Karl and others - unpublished field mapping, 1978 and 1979.
4) Robert A. Loney, Henry C. Berg, David A. Brew, and John S. Pomeroy - unpublished field mapping, 1961.
5) Loney and others, 1975.
6) Reed and Coats, 1941.
7) Rossman, 1959.
8) Photogeologic compilations by John Decker, 1977 and 1978; and by J.N. Platt, K-Ar age determinations are by Fredric H. Wilson and Donald L. Turner (Decker and others, 1980).
9) Radiolarian age determinations are by Susan Karl and David L. Jones.
10) Bioclia age determinations are by David L. Jones.

NOTE:

The textural grades used in this report are based on field observations mainly of argillite and schist with minor sandstone, conglomerate, and volcanic flow rocks and breccia, that have been subjected to low grade regional metamorphism of zeolite, prehnite-pumpellyite, greenschist, and blueschist facies. The 5 textural grades are in order of increasing metamorphic intensity (+grade(?) and are defined as follows:

TEXTURAL GRADE 1-Weakly to unrecrystallized-generally massive with no metamorphic foliation or observable minerals developed, and no metamorphic segregations or layering. Original textures, structures and minerals are locally preserved. Metamorphic effects include cataclastic fracture foliation, slaty cleavage, and a light green color in the metacalcic rocks, probably caused by incipient sericite, chlorite, and epidote minerals. Approximately equal to CHLORITE SUBZONE 1 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 2 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 2 of Blake and others (1967).

TEXTURAL GRADE 2-Very weakly foliated to massive-with incipient metamorphic foliation developed only in originally layered rocks and only well displayed on weathered surfaces. The foliation is generally difficult to measure and the rock usually breaks across the foliation. Originally massive rocks (flows, breccias, dikes, sandstone) are generally still massive but are very dense and hard. Metacalcic rocks are generally light to medium green due to finely disseminated sericite, chlorite and epidote minerals. Metacrystalline locally show a poorly developed discontinuous segregation layering of light gray to white relatively pure quartz surrounded by a matrix of dark gray argillite. Probably equal to the lower CHLORITE SUBZONE 2 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 2 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 2 of Blake and others (1967).

TEXTURAL GRADE 3-Subphyllitic-has distinct metamorphic foliation, easily observed and measured on weathered surfaces. On highly weathered surfaces, the rock breaks along the foliation planes while fresh rock breaks across the foliation generally with a star-top ragged edge where the rock breaks first along one foliation surface than another for short distances. Subphyllites have no well developed phyllitic sheen to foliation surfaces and no observable metamorphic minerals. Metacalcic rocks are generally light green, blue green, or medium green, due to very fine-grained chlorite, epidote minerals, sericite, actinolite, and/or crossite. Metacrystalline is moderately recrystallized to thin alternating layers of light gray relatively pure quartz and sericite, and dark gray layers composed of quartz, sericite, graphite and carbonate. Probably equal to the upper CHLORITE SUBZONE 2 of Hutton and Turner (1936), and to the upper GRAYWACKE TEXTURAL ZONE 3 of Blake and others (1967).

TEXTURAL GRADE 4-Phyllitic-has a well developed metamorphic foliation, and is generally fissile, especially on weathered surfaces. Metacalcic rocks are generally medium green; metamorphic minerals are still too fine-grained to be readily distinguished with a hand lens but include sericite, actinolite, blue-green hornblende, chlorite, epidote minerals, crossite, and calcite. Metacrystalline rocks are completely recrystallized, generally thinly laminated with well developed phyllitic sheen on foliation surfaces, and with locally well developed F₂ crenulations and S₂ slip cleavage. Approximately equal to the lower CHLORITE SUBZONE 3 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 3 of Blake and others (1967).

TEXTURAL GRADE 5-Fine-grained schist and phyllite-similar to TEXTURAL GRADE 4 but with identifiable metamorphic minerals, typically actinolite, muscovite blue-green hornblende, fuchsite, epidote minerals, crossite, and calcite. Metacrystalline rocks are completely recrystallized, generally thinly laminated with well developed phyllitic sheen on foliation surfaces, and with locally well developed F₂ crenulations and S₂ slip cleavage. Approximately equal to the lower CHLORITE SUBZONE 4 of Hutton and Turner (1936), and to the lower GRAYWACKE TEXTURAL ZONE 3 of Blake and others (1967).

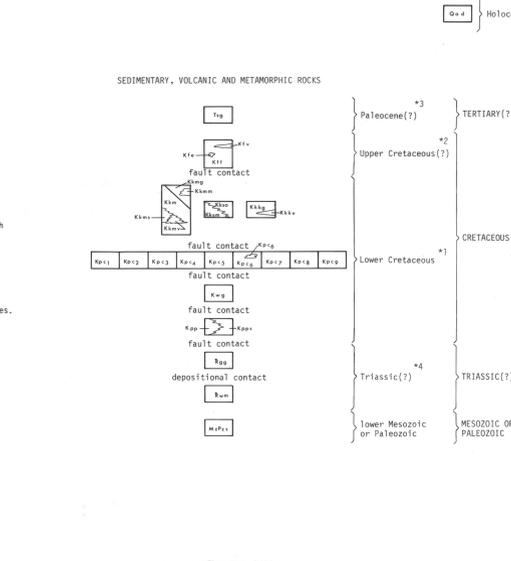

EXPLANATION

DESCRIPTION OF MAP UNITS

- ALLUVIUM AND DRIFT, undivided - Contacts taken from aerial photographs with only minor field checking.
SITKA GRAYWACKE - The Sitka Graywacke consists of light to medium gray, thick-bedded to massive, medium- to coarse-grained sandstone, with minor conglomerate, siltstone and mudstone. The sandstone is composed chiefly of quartz, calcareous fragments, plagioclase, potassium feldspar, and detrital biotite; conglomerate clasts are mainly pebbles and cobbles of felsic volcanic and plutonic rock, clastic sedimentary rock, chert, greenstone and carbonate. The Sitka Graywacke on Chichagof and Kikachuk Islands is a broken formation consisting of highly disrupted and chaotically juxtaposed strata. Dominant fault axes Ricci Lucchi turbidite facies are A and B, with minor facies F and G. These rocks probably represent an inner-fan facies association derived from a volcano-plutonic source terrane (Decker and others, 1979).
FORD ARM FLYSCH - The Ford Arm Flysch consists dominantly of sandstone and siltstone turbidites interbedded with mudstone and shaly mudstone (Kff), minor interbedded metabasalt (Kfb), and rare exotic blocks (Kfb). The sedimentary rocks are distinguished from the Sitka Graywacke on the basis of turbidite sedimentology (Sitka Graywacke is dominantly facies A and B, Ford Arm Flysch is mainly facies D and E), and sandstone petrology (detrital biotite and potassium feldspar are common in the Sitka Graywacke and rare to absent in the Ford Arm Flysch). Rocks are locally hornfelsed around Tertiary intrusives.
Sedimentary and hornfelsed sedimentary rocks, undivided - The rocks of this unit are medium to dark gray, thin- to medium-bedded, fine- to medium-grained sandstone turbidites, with minor interbedded siltstone turbidites and mudstone, and minor thick-bedded to massive sandstone and conglomerate. The sandstone is composed chiefly of quartz, volcanic rock fragments, and plagioclase; conglomerate clasts are chiefly pebbles and granules of reworked sedimentary rock, volcanic rock and carbonate. The Ford Arm Flysch is characterized by pervasive ductile deformation, rotated strata and angular tectonic blocks. Mutci and Ricci Lucchi turbidite facies are dominantly D and E with minor facies A, B, F and G. This unit is interpreted as a mid-fan facies association derived from a first-cycle volcanic source terrane (Decker and others, 1979).
Metabasalt - Rocks are dominantly medium green massive to schistose metabasalt, which occurs as turf, flow breccia and massive flows, interbedded with thin-bedded turbidites (Kff). The metabasalt locally contains limestone clasts, calcareous zones, and blocks and streaks of red chert. The schistose metabasalt has a prominent S₁ foliation with locally well developed medium-grained actinolite.
Exotic blocks near Khaz Bay - Rocks of this unit consist of a large block of silicified pillow lava and of tightly folded, highly deformed banded metachert.
KHAZ MELANGE - The Khaz Melange is a chaotic terrane characterized by exotic blocks of greenstone, greenschist, blueschist, marble, chert, fossiliferous limestone, sandstone and pillow lava, a matrix of argillite (metacrystalline) and/or turf (metaturf). The Khaz Melange is subdivided locally into two members, the Sloucm Arm Argillite Member and the Kishman Cove Graywacke Member. The formation is subdivided locally in the basis of sedimentary to volcanic ratio (Kkm and Kkmv). In Khaz Peninsula, a greenstone block (Kkg) and associated marble (Kkm) were mapped separately.
Melange, undivided - This unit consists mainly of rocks similar to units Kkm, Kkmv, Kkm, and Kkm that are either too intimately interbedded to be mapped separately, or in areas that were not studied in sufficient detail to subdivide units, or are in unstudied areas mapped as Khaz Melange by Loney and others (1975).
Dominantly metacalcic rocks - These rocks are mainly highly deformed very dark gray to black argillite and weakly foliated metacrystalline chaotically interbedded with medium green massive to subphyllitic metaturf. The sedimentary to volcanic ratio is approximately 9:1. The volcanic and metacalcic rocks are evenly distributed throughout the unit and occur as thin interbeds, streaky lenses, angular pebbles to boulder-size clasts, and large tectonic blocks. Where present, the weak metamorphic fabric was developed subsequent to melange mixing. Textural grades 1 and 2 (minor 3, but possibly in blocks).
Dominantly metacalcic rocks - These rocks are mainly highly deformed, light to medium green, massive to subphyllitic metaturf chaotically interbedded with dark gray to black argillite, and black and white, thinly laminated, tightly folded subphyllitic metacalcic rocks. The sedimentary to volcanic ratio is approximately 1:1. The volcanic and metacalcic rocks are mainly turf and tuff breccias; minor rock types include agglomerate and pillow breccia. Metacalcic rocks generally occur in discrete zones that are similar to units Kkm and are too small to map separately. Textural grades 1, 2 and 3.
Greenstone block(?) on Khaz Peninsula - This unit consists of green, gray, and rust weathering greenstone and foliated metacalcic rocks, red chert, and marble. This was mapped by Loney and others (1975).
Marble in greenstone block(?), Kkm - The rocks are massive, locally layered, light gray weathering, fine-grained to sugary marble. The marble is tightly folded and locally includes green volcanic lenses. Mapped by Loney and others (1975).
SLOUCM ARM ARGILLITE MEMBER-turbidite facies - This unit consists of dark gray to black, siltstone and mudstone turbidites interbedded with hemipelagic mudstone, with minor sandstone lenses and boudins, and no volcanic rocks. Sandstone to shale ratios is low, generally less than 1:10, but the ratio of graded to ungraded mudstone is about 1:1. The rocks are generally highly disrupted by an anastomosing fracture foliation. The turbidites are mainly Mutci and Ricci Lucchi facies D, F and G, and are interpreted to have been deposited in a submarine slope environment (Decker and others, 1979).
SLOUCM ARM ARGILLITE MEMBER-melange facies - These rocks are similar to the highly deformed zones in Kkm, but in this unit, the rocks characteristically contain minor but ubiquitous lenses and blocks of streaky green turf, and exotic blocks of higher grade metamorphic rocks, marble, fossiliferous calcareous sandstone and chert. The sedimentary to volcanic ratio is variable but averages approximately 5:1. The textural grade of the matrix is 1. The contact between the turbidite and melange facies of the Sloucm Arm Argillite Member is placed at the first occurrence of volcanic rocks and/or exotic blocks.
KISHMAN COVE GRAYWACKE MEMBER-grapevacke facies - This facies is dominantly medium gray, massive, medium- to very coarse-grained sandstone and granule conglomerate, and dark gray, highly disrupted shaly argillite and pebbly mudstone. The graywacke is locally associated with exotic blocks of chert, carbonate and volcanic rocks (Kkv). The sedimentary to volcanic ratio is very high, approximately 90:1. The graywacke appears massive in outcrop but on rare smoothly-weathered or polished surfaces, the rock can be seen to be a highly chaotic assemblage of juxtaposed fragments and vague zones of clastic sedimentary rock that vary slightly in color, grain size, sorting, bedding features and carbonate content. Limited evidence suggests that the mixing took place both during syn- and postdepositional tectonic deformation and as ductile tectonic deformation of unithrifted strata. Turbidite facies nomenclature can rarely be applied to the textures suggest deposition in a relatively proximal- to lower slope or inner fan-environment.
KISHMAN COVE GRAYWACKE MEMBER-volcanic rocks and/or exotic blocks - These rocks occur as mappable bodies or as isolated zones of interbedded streaky green turf, tightly folded, yellow weathering, gray banded chert, red radiolarian chert, volcanic breccia, pillow lava, calcareous sandstone or marble. The most typical association is volcanic breccia, turf, yellow weathering chert, and locally, red radiolarian chert.
PINTA BAY COMPLEX - The Pinta Bay Complex is composed of an assemblage of mainly fault-bound tectonic terranes, each with a characteristic lithologic association, deformational style and/or metamorphic grade. The metacalcic rocks are chemically andesite and basalt; the metacalcic rocks were originally fine-grained clastic rocks, dominantly siltstone and mudstone.
Unit 1 - Unit 1 consists of fine-grained shaly mudstone with minor siltstone and turf. The sedimentary to volcanic ratio is approximately 1:1. The volcanic rocks are locally present but are generally distributed throughout the unit and generally occur as interbedded fragments with irregularly wavy to streaky contacts with the sedimentary rock. Locally, the sedimentary and volcanic rocks are thinly inter-layered. Unit 1 is highly disrupted by a pervasive anastomosing fracture foliation but shows no evidence of metamorphic segregation or development of a regional metamorphic fabric. Textural grade 1.
Unit 2 - These rocks are fine-grained shaly mudstone and turf, with minor siltstone and marble. The sedimentary to volcanic ratio is very similar to unit 1 but unit 2 has a sedimentary to volcanic ratio of approximately 1:1. Textural grade 1. Units 1 and 2 are similar to rocks of the Khaz Melange, particularly units Kkm, Kkmv, and Kkm, but they however contain much less sandstone, have a more systematic structure and lack exotic blocks (other than turf and rare pillow basalt).
Unit 3 - Unit 3 consists dominantly of light to medium green subphyllitic to phyllitic metacalcic rocks with discrete zones of dark gray to black and white thinly layered, highly contorted phyllitic metacalcic rocks, and minor marble and calcareous nodules. Sedimentary to volcanic ratio is 1:9. Metamorphic foliation is well developed with locally visible chlorite and actinolite. Textural grade 4.
Unit 4 - This unit consists of dark gray to black and white thinly layered phyllitic metacalcic rocks and medium green phyllitic to schistose metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with about 10 percent foliated marble, and ubiquitous wavy-weathering phyllitic sheen on rocks are completely recrystallized with well developed phyllitic sheen on foliation surfaces and with locally present F₂ crenulations and S₂ slip cleavage. Metacalcic rocks are composed chiefly of quartz, sericite and graphite; the metacalcic rocks are composed mainly of chlorite, actinolite, epidote, blue-green hornblende, calcite, quartz and fuchsite. Textural grade 5.
Unit 5 - Unit 5 consists of greenish gray, massive, internally chaotic crystalline turf and tuff breccia. No clastic sedimentary rocks were seen. The majority of the unit is fine-grained massive turf (70 percent), with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 6 - North of Goon Dip Mountain, unit 6 consists of light to medium green, massive to very weakly foliated metacalcic rocks, and internally inter-layered, incompletely recrystallized, weakly foliated, dark gray metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 6 - Marble at Goon Dip Mountain mapped by Reed and Coats (1941). The marble is fine-grained, pure and has a wavy-weathering and weathers gray with rough surfaces; contains considerable volcanic material.
Unit 7 - Unit 7 consists of dominantly light to medium green, massive to subphyllitic metacalcic rocks, and dark gray to black and white, thinly layered metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 8 - Unit 8 is dominantly light to medium green subphyllitic to phyllitic metacalcic rocks with lesser amounts of massive light green greenstone, and minor highly deformed phyllitic metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 9 - Unit 9 consists mainly of highly contorted, dark gray to black and white, thinly layered subphyllitic and phyllitic metacalcic rocks (50 percent), internally and interbedded metaturf and metacalcic rocks (50 percent) and massive light greenstone (10 percent). The sedimentary to volcanic ratio is approximately 3:2, with no marble. Where metacalcic rocks predominate, the structure is generally complex, but not chaotic. These rocks are very tightly folded and intensely faulted, they generally have a well developed S₁ foliation with locally well developed F₂ crenulations and rare S₂ slip cleavage. The rocks are locally rich in white chalky weathering laminites. Textural grades 2, 3 and 4. Unit 9 is compositionally similar to unit 8 but is higher textural grade but unit 9 is a higher textural grade and less chaotic.
WATERFALL GREENSTONE - The Waterfall Greenstone is generally massive, highly altered, reddish weathering greenstone with varying amounts of orange weathering graywacke and turf, and minor cherty weathering red and gray radiolarian chert. The chert occurs both as tightly folded blocks of bedded chert and as strongly chaotic and pieces chaotically interbedded with the greenstone. Mixing of the second type of chert probably occurred during a volcanic event while the chert was still soft radiolarian ooze. Two of these chert samples were analyzed by Susan Karl and David L. Jones of the U.S. Geological Survey and have yielded age-determinations of Valangian (Early Cretaceous) age. The greenstone locally contains metacalcic rocks and structures that indicate they were originally massive flows, pillow lavas, flow breccia and turf. Textural grade 1.
PINNACLE PEAK PHYLITE - The Pinnacle Peak Phyllite consists of phyllitic to phyllitic metacalcic rocks with lesser amounts of phyllitic metacalcic rocks and slightly recrystallized to subphyllitic metacalcic rocks (Kpp).
Subphyllitic to phyllitic metacalcic and sedimentary rocks - The sedimentary to volcanic ratio is locally highly variable but overall is approximately 3:1. Metacalcic rocks are generally dark gray with thin white quartz-sericite segregation layers; the metacalcic rocks are light to medium green, locally with thin white quartz layers and both rocks have thin white quartz-sericite segregation layers, generally with a strong phyllitic sheen. F₁ fold axes are present but rare; F₂ crenulations and minor folds, and S₂ slip cleavage are common. Locally, the rocks have a superimposed D₁ deformation characterized by complex apparently unsystematic F₃ folds and brittle fracture. Textural grade 2.
Slightly recrystallized to subphyllitic metacalcic rocks - The sedimentary to volcanic ratio is very high, approximately 20:1. The rocks locally retain original sedimentary features that indicate that they were originally thin- to medium-bedded (2 to 10 cm thick) turbidites with a sandstone to shale ratio of approximately 1:1. The coarsest grain size observed was fine sand (up to 0.25 mm), grading is fine and gradation is common and gradation is locally folded. These rocks grade into dark gray to black and white thinly layered subphyllitic rocks of Kpp. Textural grades 2 and 3.
GOON DIP GREENSTONE - The Goon Dip Greenstone is generally massive, medium gray weathering, medium to dark gray and greenish gray, fine-grained, plagioclase- (or rarely pyroxene-) porphyritic basalt and metabasalt. The rocks are dominantly massive, holocrystalline, commonly emphyloidal, and locally pillowed. Pillow breccia, flow breccia, and crystalline pillow tuff are less common, and diabase dikes are rare. Locally, the rocks have a very weakly developed metamorphic foliation. Textural grade 1.
WHITESTRIPE MARBLE - The Whitestripe marble is generally massive to weakly foliated, white to medium gray, fine-grained marble, locally; it includes medium- to coarse-grained, lenses and pieces, and diorite dikes; only the larger bodies of each are mapped separately.
SILICEOUS METASEDIMENTARY ROCKS - These rocks are dominantly thin- to medium-bedded various shades of gray quartzite and impure quartzite, including recrystallized chert, argillite, siltstone and sandstone. The age is uncertain but the rocks are closely associated with the Goon Dip Greenstone and are intruded by diorite plutons.
DAVISON BAY COMPLEX - A complex stock of norite (Nn), gabbro (Gg), and tonalite (Tt); minor rock types include amphibole, amphibolite, marble, diorite, monzonite, granite, pegmatite, quartz veins and schists including (Pecora, 1942; Rossman, 1959). A mid-Tertiary age is inferred by Rossman (1959).
Norite - This unit consists of norite and associated rocks, and includes copper-nickel deposits of pyrrhotite, chalcopyrite and pentlandite. Mapped by Pecora (1942), and Rossman (1959).
Gabbro - This unit consists of gabbro and associated rocks mapped by Pecora (1942), and Rossman (1959).
Tonalite - This unit is dominantly tonalite and quartz diorite, mapped by Rossman (1959).
GRANDIORITE - Grandiorite in the Khaz Bay area consists of massive, leucocratic (Cl = 10-15), medium-grained biotite granodiorite. The age is based on two K-Ar biotite dates of 46.6 m.y. and 48.2 m.y.
GRANDIORITE - Grandiorite in the Hirst Mountain area, consists of massive, light colored (Cl = 10-15), medium-grained hornblende-biotite granodiorite. The age is inferred from structural position and regional correlation with isotopically dated similar rocks (Loney and others, 1975). May be Tertiary.
DIORITE - This unit is highly variable in composition but in general consists of massive to weakly foliated, dark colored (Cl = 25-40), fine- to medium-grained biotite-hornblende diorite, and quartz diorite. The age is uncertain but the rocks are closely associated with the Goon Dip Greenstone and are intruded by diorite plutons.
TONALITE - The tonalite unit consists of foliated, Cl = 20-25, medium-grained biotite-hornblende tonalite and quartz diorite. The age is based on a local correlation with isotopically dated similar rocks (Loney and others, 1975).

CORRELATION OF MAP UNITS

- Unit 4 - This unit consists of dark gray to black and white thinly layered phyllitic metacalcic rocks and medium green phyllitic to schistose metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with about 10 percent foliated marble, and ubiquitous wavy-weathering phyllitic sheen on rocks are completely recrystallized with well developed phyllitic sheen on foliation surfaces and with locally present F₂ crenulations and S₂ slip cleavage. Metacalcic rocks are composed chiefly of quartz, sericite and graphite; the metacalcic rocks are composed mainly of chlorite, actinolite, epidote, blue-green hornblende, calcite, quartz and fuchsite. Textural grade 5.
Unit 5 - Unit 5 consists of greenish gray, massive, internally chaotic crystalline turf and tuff breccia. No clastic sedimentary rocks were seen. The majority of the unit is fine-grained massive turf (70 percent), with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 6 - North of Goon Dip Mountain, unit 6 consists of light to medium green, massive to very weakly foliated metacalcic rocks, and internally inter-layered, incompletely recrystallized, weakly foliated, dark gray metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 6 - Marble at Goon Dip Mountain mapped by Reed and Coats (1941). The marble is fine-grained, pure and has a wavy-weathering and weathers gray with rough surfaces; contains considerable volcanic material.
Unit 7 - Unit 7 consists of dominantly light to medium green, massive to subphyllitic metacalcic rocks, and dark gray to black and white, thinly layered metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 8 - Unit 8 is dominantly light to medium green subphyllitic to phyllitic metacalcic rocks with lesser amounts of massive light green greenstone, and minor highly deformed phyllitic metacalcic rocks. The sedimentary to volcanic ratio is approximately 3:2, with lesser amounts of red radiolarian chert-rich turf and tuff breccia (10 percent), crystalline turf breccia with a cherty and/or calcareous matrix (10 percent), and exotic blocks of banded marble with a recrystallized cataclastic foliation (10 percent). Breccia clasts generally weather yellow green to light greenish yellow and contain phenocrysts of altered pyroxene and plagioclase. Turf is locally yellow due to interstitial carbonate. The rocks are generally very dense with no metamorphic foliation. The rocks locally contain abundant pyrite and minor chalcopyrite. Textural grade 1.
Unit 9 - Unit 9 consists mainly of highly contorted, dark gray to black and white, thinly layered subphyllitic and phyllitic metacalcic rocks (50 percent), internally and interbedded metaturf and metacalcic rocks (50 percent) and massive light greenstone (10 percent). The sedimentary to volcanic ratio is approximately 3:2, with no marble. Where metacalcic rocks predominate, the structure is generally complex, but not chaotic. These rocks are very tightly folded and intensely faulted, they generally have a well developed S₁ foliation with locally well developed F₂ crenulations and rare S₂ slip cleavage. The rocks are locally rich in white chalky weathering laminites. Textural grades 2, 3 and 4. Unit 9 is compositionally similar to unit 8 but is higher textural grade but unit 9 is a higher textural grade and less chaotic.
WATERFALL GREENSTONE - The Waterfall Greenstone is generally massive, highly altered, reddish weathering greenstone with varying amounts of orange weathering graywacke and turf, and minor cherty weathering red and gray radiolarian chert. The chert occurs both as tightly folded blocks of bedded chert and as strongly chaotic and pieces chaotically interbedded with the greenstone. Mixing of the second type of chert probably occurred during a volcanic event while the chert was still soft radiolarian ooze. Two of these chert samples were analyzed by Susan Karl and David L. Jones of the U.S. Geological Survey and have yielded age-determinations of Valangian (Early Cretaceous) age. The greenstone locally contains metacalcic rocks and structures that indicate they were originally massive flows, pillow lavas, flow breccia and turf. Textural grade 1.
PINNACLE PEAK PHYLITE - The Pinnacle Peak Phyllite consists of phyllitic to phyllitic metacalcic rocks with lesser amounts of phyllitic metacalcic rocks and slightly recrystallized to subphyllitic metacalcic rocks (Kpp).
Subphyllitic to phyllitic metacalcic and sedimentary rocks - The sedimentary to volcanic ratio is locally highly variable but overall is approximately 3:1. Metacalcic rocks are generally dark gray with thin white quartz-sericite segregation layers; the metacalcic rocks are light to medium green, locally with thin white quartz layers and both rocks have thin white quartz-sericite segregation layers, generally with a strong phyllitic sheen. F₁ fold axes are present but rare; F₂ crenulations and minor folds, and S₂ slip cleavage are common. Locally, the rocks have a superimposed D₁ deformation characterized by complex apparently unsystematic F₃ folds and brittle fracture. Textural grade 2.
Slightly recrystallized to subphyllitic metacalcic rocks - The sedimentary to volcanic ratio is very high, approximately 20:1. The rocks locally retain original sedimentary features that indicate that they were originally thin- to medium-bedded (2 to 10 cm thick) turbidites with a sandstone to shale ratio of approximately 1:1. The coarsest grain size observed was fine sand (up to 0.25 mm), grading is fine and gradation is common and gradation is locally folded. These rocks grade into dark gray to black and white thinly layered subphyllitic rocks of Kpp. Textural grades 2 and 3.
GOON DIP GREENSTONE - The Goon Dip Greenstone is generally massive, medium gray weathering, medium to dark gray and greenish gray, fine-grained, plagioclase- (or rarely pyroxene-) porphyritic basalt and metabasalt. The rocks are dominantly massive, holocrystalline, commonly emphyloidal, and locally pillowed. Pillow breccia, flow breccia, and crystalline pillow tuff are less common, and diabase dikes are rare. Locally, the rocks have a very weakly developed metamorphic foliation. Textural grade 1.
WHITESTRIPE MARBLE - The Whitestripe marble is generally massive to weakly foliated, white to medium gray, fine-grained marble, locally; it includes medium- to coarse-grained, lenses and pieces, and diorite dikes; only the larger bodies of each are mapped separately.
SILICEOUS METASEDIMENTARY ROCKS - These rocks are dominantly thin- to medium-bedded various shades of gray quartzite and impure quartzite, including recrystallized chert, argillite, siltstone and sandstone. The age is uncertain but the rocks are closely associated with the Goon Dip Greenstone and are intruded by diorite plutons.
DAVISON BAY COMPLEX - A complex stock of norite (Nn), gabbro (Gg), and tonalite (Tt); minor rock types include amphibole, amphibolite, marble, diorite, monzonite, granite, pegmatite, quartz veins and schists including (Pecora, 1942; Rossman, 1959). A mid-Tertiary age is inferred by Rossman (1959).
Norite - This unit consists of norite and associated rocks, and includes copper-nickel deposits of pyrrhotite, chalcopyrite and pentlandite. Mapped by Pecora (1942), and Rossman (1959).
Gabbro - This unit consists of gabbro and associated rocks mapped by Pecora (1942), and Rossman (1959).
Tonalite - This unit is dominantly tonalite and quartz diorite, mapped by Rossman (1959).
GRANDIORITE - Grandiorite in the Khaz Bay area consists of massive, leucocratic (Cl = 10-15), medium-grained biotite granodiorite. The age is based on two K-Ar biotite dates of 46.6 m.y. and 48.2 m.y.
GRANDIORITE - Grandiorite in the Hirst Mountain area, consists of massive, light colored (Cl = 10-15), medium-grained hornblende-biotite granodiorite. The age is inferred from structural position and regional correlation with isotopically dated similar rocks (Loney and others, 1975). May be Tertiary.
DIORITE - This unit is highly variable in composition but in general consists of massive to weakly foliated, dark colored (Cl = 25-40), fine- to medium-grained biotite-hornblende diorite, and quartz diorite. The age is uncertain but the rocks are closely associated with the Goon Dip Greenstone and are intruded by diorite plutons.
TONALITE - The tonalite unit consists of foliated, Cl = 20-25, medium-grained biotite-hornblende tonalite and quartz diorite. The age is based on a local correlation with isotopically dated similar rocks (Loney and others, 1975).
