TABLES--Continued

Introduction

A geochemical survey was done in the Medfra quadrangle, west-central Alaska during 1978 and 1979 as part of the Alaska Mineral Resource Assessment Program (AMRAP). This report presents analytical data (tables 6-9) and statistical summaries of the analytical data (tables 1-4) from this survey. Analytical results for part of the samples collected during 1978 were previously published (King and others, 1979) and are included in this report.

This report includes analytical and statistical data for 513 <0.177 mm (minus-80 mesh) stream-sediment samples, 370 nonmagnetic heavy-mineral concentrate samples, 422 moderately magnetic heavy-mineral concentrate samples, and 355 samples of ash of aquatic bryophytes (mosses).

Samples were collected from a total of 517 sites. Access to sample sites was gained by use of a helicopter. Sample site locations are shown on plate 1.

Sampling and description of sample media

The quadrangle is, in large part, covered by dense vegetation, particularly along the streams. The availability of helicopter landing sites often determined at what point along the stream the samples would be taken. Most of the samples were taken from channels of active streams with upstream catchment areas averaging about nine km^2. Samples were taken from first or second order streams whenever possible. Larger, or third order, streams were sampled when landing sites along first or second order tributary streams were not available.

Minus-2-mm stream sediment was collected for the stream sediment samples by wet sieving at the sample sites with a stainless-steel screen. Heavy-mineral concentrate samples were collected by panning the minus-2-mm stream sediment to remove most of the light mineral fraction.

Samples of aquatic bryophytes (mosses) were collected from stream channels beneath the water level mainly from the silty sides of the stream channels but also from deadwood and boulders where they were attached. Samples were partially washed in the stream at the sample sites to remove large quantities of silt and sand. No attempt was made to differentiate the various species of bryophytes which were collected.

Lowland areas, including as much as 3,900 km^2, mainly in the south and southeastern parts of the quadrangle were not sampled because they are covered by thick unconsolidated deposits of Quaternary material and geochemical sampling techniques that might be effective in these areas were not within the scope of this survey.

Preparation of samples

All samples were partially dried in the field and later completely dried in an oven at the laboratory. After drying, the stream-sediment samples were sieved with an 80-mesh (0.177 mm) screen and the <80-mesh fraction was pulverized to minus 150 mesh in a vertical grinder using ceramic grinding plates. Panned samples were sieved with a 20-mesh (0.8 mm) screen to remove coarse material which would not pass readily through laboratory equipment used in the bromoform and magnetic separation procedures. The >20 mesh fraction, which in most cases, included only a small volume percent of the total sample, was scanned visually for the presence of heavy minerals, and discarded. The <20-mesh fraction was passed through bromoform (specific gravity, 2.86) to remove light-mineral grains not removed in the panning process. Each heavy-mineral concentrate sample was then divided into three fractions based on the magnetic susceptibilities of the mineral grains. A fraction consisting chiefly of magnetite was removed with the use of a hand magnet and a Frantz[1/]

---

[1]The use of this trade name is for descriptive purposes only and does not constitute endorsement of this product by the U.S. Geological Survey.

Isodynamic magnetic separator. In using the separator to remove magnetite, the samples were passed closely beneath the separator with the track removed, the magnetic poles oriented vertically downward and covered, and with the current set at 2 amperes. Two additional fractions were

obtained by passing the remaining sample through the Frantz separator at a setting of 0.6 ampere. The fraction composed of mineral grains having no magnetic susceptibility to 0.6 ampere is referred to in this report as the nonmagnetic or the C-3 fraction. (The nonmagnetic fraction generally contains most of the minerals of interest in geochemical exploration.) Subsequent to this separation the mineralogic composition of the C-3 (nonmagnetic) fraction was determined by visual observation with a binocular microscope. X-ray diffraction was used to verify the identification of some mineral grains. The fraction consisting of mineral grains with magnetic susceptibilities between 0.1 and 0.6 ampere is referred to in this report as moderately magnetic, or the C-2 fraction. Using a microsplitter a split of each sample of the C-2 and C-3 fraction was obtained. One split was then pulverized to <150 mesh by hand grinding in a mortar and pestle. The ground portion was used for spectrographic analysis.

After oven drying the samples of aquatic bryophytes most remaining silt and sand was removed by hand and compressed air followed by several rinses with tap water. The samples were again oven dried, pulverized in a blender, and ashed in a muffel furnace during a 24-hour period with a maximum temperature of 500°C. The ash was passed through a 0.119 mm sieve (145 mesh) to remove most remaining sand grains. The ash of the samples ranged from 8 to 72 percent with a mean weight of 36 percent of the dry material. The ash of aquatic bryophytes that are free of sediment should be approximately 10 percent of the original dry weight (Brooks, 1972, p. 178). Thus, most samples contained various undertermined amounts of sediment.

Methods of analysis

Stream-sediment and the C-2 and C-3 heavy-mineral concentrate samples were analyzed semiquantitatively for 31 elements using a six-step emission spectrographic method outlined by Grimes and Marranzino (1968). The spectrographic results were reported as geometric midpoints, 1.0, 0.7, 0.5, 0.3, 0.2, 0.15, (or appropriate multiples of ten) of geometric brackets having the boundaries 1.2, 0.83, 0.56, 0.38, 0.26, 0.18, 0.12, (or appropriate multiples). The method was modified slightly for the concentrate samples to eliminate spectral interferences. The modification consisted of using half the amount of sample, 5 mg. For samples 308-517, and 178, a 10-mg standard was used for the 5-mg samples, and concentrations determined by visual comparisons were doubled. Doubled values occurring between geometric midpoints were rounded to the next higher midpoint. For samples 1-306, except 178, half the amount of standard (5 mg) was used for the 5-mg samples and concentrations determined by visual comparisons were reported directly. The difference in the amount of standard used resulted in differences in reported upper limits of determination as indicated in table 5. Stream-sediment samples were also analyzed for gold, mercury, and zinc using atomic-absorption (methods described by Ward and others, 1969).

Ash samples of aquatic bryophytes were analyzed for 33 elements by a semiquantitative emission spectrographic method for plant materials described by Mosier (1972) and modified by Curry and others (1975). These 33 elements include the elements analyzed in the sediment and concentrate samples, with the exception of calcium, scandium, and thorium, and include five additional elements: sodium, gallium, germanium, indium, and thallium.

Stream-sediment and heavy-mineral concentrate samples collected from sites 1-308, except concentrate samples from site 178, and all samples of ash of aquatic bryophytes were analyzed spectrographically by E. F. Cooley. Sediments from sites 309-516 were analyzed spectrographically by D. A. Risoli and J. T. Hurrell. Concentrate samples from sites 309-517, and 178 were analyzed spectrographically by D. A. Risoli. Atomic-absorption analyses were performed by R. M. O'Leary, A. L. Gruzensky, and G. Y. Ito.

Explanation of data

Summarized statistics based on the analytical data for stream sediments, moderately magnetic heavy-mineral concentrates, nonmagnetic heavy-mineral concentrates, and samples of ash of aquatic bryophytes are given in tables 1-4, respectively.

Tables 6-9 contain analytical results for <80-mesh stream-sediment, moderately magnetic heavy-mineral concentrate, nonmagnetic heavy-mineral concentrate, and ash of aquatic bryophytes samples, respectively. Limits of determination are given in table 5. Symbols used in the tables are as follows: <, an undetermined value less than the value shown was detected; N, not detected; >, an undetermined value greater than the value shown was detected. The symbols "S," "AA," and "INST" in the element column headings preceding the element symbols indicate the method of analysis as follows: S, spectrographic analysis; AA, INST, atomic absorption analysis.

Sample numbers, given in the tables, coincide with sample numbers shown on the map (plate 1). The site numbers may be obtained from sample numbers by removing the prefix M, leading zeros, and suffixes S, C2, C3, or M. For example, the site where sample number M001S was collected is indicated by a dot on the map next to the number 1.

All of the analytical data have been entered in the U.S. Geological Survey's computerized analysis storage system (RASS).

The value of ten parts per million gold reported for semiquantitative spectrographic analysis of sample M272S is suspect. Gold was the only element reported in an unusual amount in this sample and gold was not detected by atomic absorption analysis. Two additional splits of this sample weighing 1 g and 10 g were analyzed by atomic absorption (analyses by J. D. Sharkey) with no gold detected.
