# CHEMANAL: A MULTICS Fortran program to calculate chemical weathering data

by

Steven M. Colman

Open-File Report 80-844

1980

# INTRODUCTION

This program is written in MULTICS Fortran, and calculates various chemical-weathering data from weight-percentage data. The input data file is a matrix with each row representing one sample, and each column representing one category of data. The input data matrix is composed of weight-percentage data for each sample (row) in the following format:

| Column | Data | Format |
|---|---|---|
| 1 | Sample name | A8 |
| 2 | Sample interval | A8* |
| 3 | Bulk density | F6.2 |
| 4 | SiO2 | " |
| 5 | Al2O3 | " |
| 6 | Fe2O3 | " |
| 7 | FeO | " |
| 8 | MgO | " |
| 9 | CaO | " |
| 10 | Na2O | " |
| 11 | K2O | " |
| 12 | TiO2 | " |
| 13 | P2O5 | " |
| 14 | MnO | " |
| 15 | CO2 | " |
| 16 | H2O+ | " |
| 17 | H2O- | " |
| 18 | Sum (of wt %'s) | " |

*If (and only if) the first four spaces in this field are blank, the program treats the sample as a sample of the unweathered parent material, and calculates data normalized for the composition of the parent material. (See (2) and (5) below.)

To run the program, type "chemanal" (without quotes). The program will prompt the user for the name of the input data file, the starting and ending row numbers, the type of output, and the output file names.

Depending on user response to prompt questions, output files with the following types of data will be produced:

1. Weight percentages: This is the input data and will always be included in the output. TiR (ratio of TiO2 in the unweathered parent material to that in the weathered sample) is calculated and included.
2. Molecular percentages, molecular ratios, and molecular ratios normalized to the composition of the parent material. Molecular ratios include:
   (1) WPI and PI--Weathering potential index and product index (Reiche, 1943,1950).
   (2) Parkin--Parkinson's (1970) index.
   (3) Si:R2 and Ba:R2--Ratios of SiO2 and bases (sum of Na2O, K2O, CaO, and MgO), respectively, to R2O3 (sum of Al2O3, Fe2O3, and TiO2) (Jenny, 1941).
   (4) Fe3Fe2--Ratio of Fe2O3 to FeO.
   (5) TriSi, TriR2, and TriBas--Percentages of SiO2, R2O3, and bases, respectively, for a triangular diagram with their sum as 100 percent.
3. Standard-cell cations -- cations in a standard cell containing 160 oxygens (Barth, 1948).
4. Weights, assuming isovolumetric weathering, calculated from bulk densities.
5. Weights, assuming TiO2 constant, calculated from the ratio of TiO2 in the unweathered parent material to that in the weathered sample. Weights, assuming TiO2 constant, normalized to the composition of the parent material, are also calculated.

Notes:

1. The program makes no provision for qualified data (for example, "less than").
2. The program treats FeO and Fe2O3 separately. If these two are to be combined, the combination should be made by recalculating the original analysis before data entry.
3. Molecular percentages and standard-cell cations are calculated using only H2O+, not H2O-.
4. The calculations for normalized molecular ratios and weights assuming TiO2 constant require that a parent-material reference sample be identified (input data matrix, column 2).
