DRAINAGE AREAS OF SELECTED SURFACE-WATER SITES IN FLORIDA

By Donald W. Foose

ABSTRACT

Drainage areas for about 1,600 surface-water sites on streams and lakes in Florida are contained in this report. The sites are generally either U.S. Geological Survey gaging stations or the mouths of gaged streams. Each site is identified by latitude and longitude, by the general stream type, and by the U.S. Geological Survey 7 1/2-minute topographic map on which it can be located. The gaging stations are further identified by a downstream order number, a county code, and a nearby city or town. In addition to drainage areas, the surface areas of lakes are shown for the elevation given on the topographic map. These data were retrieved from the Surface Water Index developed and maintained by the Hydrologic Surveillance Section of the Florida District Office, U.S. Geological Survey.

GENERAL DISCUSSION OF DRAINAGE AREAS

A surface stream or a body of impounded surface water (a lake, pond, reservoir, or swamp) together with all tributary surface streams and bodies of impounded surface water occupies a part of the Earth's surface known as a drainage basin. The drainage basin includes the area up to the highest points between it and all other adjacent basins; a line connecting these points of highest elevation is called the basin boundary. The line is also the boundary for the adjacent basins and when considered in that context is called the basin divide.

The basin divide is most often the natural crest of the area between the water features, but manmade structures such as dams, levees, dikes, and road grades are designed to interrupt the flow of water and can become the basin divide. Canals, ditches, and culverts often breach natural divides and can alter basin boundaries also.

The drainage boundary encloses an area from which direct surface runoff from precipitation normally drains overland by gravity into the stream or impounded body of surface water. This area is measured, in a horizontal plane, on a map or aerial photograph and defined as the drainage area for the basin. It is generally assumed that the area that contributes direct surface runoff is coterminous with the area that contributes ground-water flow. It should be recognized, however, that ground-water drainage divides can deviate considerably from the topographic surface divide.

Drainage areas can also be determined for any point on a stream. Intermediate basin divides connect the point with the basin boundary and define an intermediate area. This intermediate area is the entire part of the basin that contributes surface runoff to the water feature at that point. If it is necessary to know what part of a basin contributes surface runoff below one point and above another, two intermediate basin divides define the intervening area.

A basin contained within a larger basin generally contributes direct surface runoff to the larger basin. If it does not, it is called a closed or noncontributing basin. A basin may also be considered partially non-contributing when direct surface runoff stops below a certain elevation. The drainage areas in this report include noncontributing and partially non-contributing areas except when noted.

EXPLANATION OF DATA

The information for selected sites is separated into tabulations for streams and lakes, and listed in downstream order within the cataloging unit of the hydrologic unit classification system. Hydrologic unit names and numbers and the area for the individual units are shown in table 1 as adapted from Florida Bureau of Geology Map Series No. 72 (Conover and Leach, 1975). An explanation of the information in each column of the computer-generated tabulation that comprises the main body of the report follows:

Site number.--The site number is the downstream order number for those locations where data have been collected. Where no number is shown the location is most often the mouth of a gaged stream but in some cases the location is where a stream crosses the state line or where an ungaged tributary stream enters the principal stream.

Name and location.--The surface-water data collection sites in this report follow the procedure established by the U.S. Geological Survey for naming gaging stations. They are given names that reflect the specific and generic names of the water feature, an indicator of distance, and the name of a nearby city or town. To avoid confusion between sites that would ordinarily have the same name, a second more specific location is occasionally added for clarity.

Site type (streams only).--Indicates the type of stream location for which the area has been determined. The codes are:

- SW - Surface Water (natural stream with a defined channel)
- SL - Slough (natural stream without a defined channel)
- DR - Drain (a naturally occurring overflow channel)
- CN - Canal (manmade stream with a defined channel)
- DD - Drainage Ditch (manmade overflow channel)
- RE - Reservoir (manmade lake)
- SP - Spring
- OT - Other

Drainage area and drainage area qualifier.--The drainage area is shown in square miles and rounded as follows:

- 0.01 square mile for areas less than 10 square miles;
- 0.1 square mile for areas 10 to 99.9 square miles;
- 1 square mile for 100 square miles or above.

Precision is affected by several circumstances. When maps other than 7 1/2-minute U.S. Geological Survey quadrangles are used, where the headwaters of two or more streams arise in the same swamp, where water is interchanged between basins, or where low relief is present, the resulting drainage area is rounded one more place and qualified approximate. For even less reliability, the results are rounded two (or more) places and qualified about. Less confidence than any of the above does not justify a basin boundary and the area is considered indeterminate. If noncontributing areas have been determined, the qualifier NONCONTR is used.

* For streams originating in Georgia and Alabama.

Surface area at elevation (lakes only).--The surface area of lakes is shown in acres as delineated on the 7 1/2-minute topographic maps. It includes only the area bounded by the continuous darker blue shoreline and excludes islands. It is valid only for the elevation shown on the map.

Latitude-longitude.--The location of the site in degrees, minutes, and seconds.

Quadrangle name.--The name of the U.S. Geological Survey 7 1/2-minute topographic map on which the site is located.

County code.--The numerical code for Florida counties as outlined in the National Bureau of Standards Publication FIPS-5-1 and 6-1. Table 2 lists the counties and codes.

Table 2.--Codes for counties in Florida

FLORIDA DRAINAGE BASINS

Florida has 30 stream systems that have a major impact because of their size or location. Table 3 lists these streams and the bodies of water which receive runoff from them.

Table 3.--Major stream systems in Florida

Stream	Outfall
St. Marys River	Cumberland Sound
St. Johns River	Atlantic Ocean
Oklawaha River	St. Johns River
Kissimmee River	Lake Okeechobee
Taylor Creek	Lake Okeechobee
Fisheating Creek	Lake Okeechobee
Lake Okeechobee outflow	Bays - Atlantic Ocean to Gulf of Mexico
Peace River	Charlotte Harbor
Myakka River	Charlotte Harbor
Manatee River	Tampa Bay
Little Manatee River	Tampa Bay
Alafia River	Hillsborough Bay
Hillsborough River	Tampa Bay
Withlacoochee River	Gulf of Mexico (Withlacoochee Bay)
Waccasassa River	Gulf of Mexico (Waccasassa Bay)
Suwannee River	Gulf of Mexico
Alapaha River	Suwannee River
Withlacoochee River	Suwannee River
Santa Fe River	Suwannee River
Aucilla River	Gulf of Mexico
St. Marks River	Gulf of Mexico (Apalachee Bay)
Ochlockonee River	Ochlockonee Bay
Apalachicola River	Apalachicola Bay
Chipola River	Apalachicola River
Yellow River	Blackwater Bay
Shoal River	Yellow River
Blackwater River	Blackwater Bay
Choctawhatchee River	Choctawhatchee Bay
Escambia River	Escambia Bay
Perdido River	Perdido Bay

Only one of the streams in table 3 terminates in the Atlantic Ocean. Six terminate in other streams, three terminate in Lake Okeechobee, five terminate in the Gulf of Mexico, and the rest terminate in bays.

Hydrologic unit (see table 1) boundaries are generally based on basin divides and can be considered coterminous with some important exceptions: notably the Florida gulf coast bays, Florida Bay, the Big Cypress Swamp, and Lake Okeechobee.

Water flow over much of southeast Florida is controlled by canals, dikes, storage in impoundments, and other manmade control devices so that natural divides do not apply and drainage areas are meaningless. The drainage pattern of some streams such as the Caloosahatchee and Kissimmee Rivers and Reedy and Shingle Creeks have been so changed by manmade structures that the drainage areas as formerly determined have been revised to indeterminate.

Springs and canals would not ordinarily have a meaningful drainage area. Some canals are "improved" streams and retain some stream characteristics. A good example is Sumter Creek Canal in west-central Florida. In such instances drainage areas with appropriate qualifiers can then be determined.

There are two large noncontributing areas in Florida: Approximately 50 square miles near Bennett in northern Florida called the Deadenings and approximately 650 square miles near Gainesville in central Florida called Paynes Prairie. Numerous other minor noncontributing areas exist, however. These are generally karsted areas characterized by sinkholes. Many lakes and ponds have no perennial outlets and have drainage areas that are either non-contributing or partially noncontributing to the stream basin in which they are located.

Many Florida river systems have their headwaters in swamps. The St. Johns River, for example, flows out of the St. Johns Marsh which extends into St. Lucie County. The St. Marys and Suwannee Rivers originate in the extensive Okefenokee Swamp of southern Georgia. The Econfinia, Fenholloway, and Steinhatchee Rivers and Spring Warrior Creek originate in San Pedro Bay. The Green Swamp is the headwaters of three major river systems, the Withlacoochee (including the Little Withlacoochee), the Oklawaha, and the Hillsborough Rivers. When more than one stream originates in a swamp, the drainage area for the swamp, in the absence of field data to the contrary, is divided midway between the channels of the affected streams.

Several streams in Florida disappear underground. The Aucilla River in Jefferson County, Lost Creek and the St. Marks River in Wakulla County, Little River in Suwannee County, Falling Creek and Rose Creek in Columbia County, the Alapaha River in Madison County, the Little Alapaha Rivers in Hamilton County, Norton Creek in Madison County, and the Santa Fe River in Alachua County among others. The drainage area for some of these streams is sometimes considered to end at the point the stream enters the ground and is a closed basin, but for others the water can reasonably be determined to emerge at a point down-gradient in the same stream or at a point on a larger stream. As has been discussed above, the closed basin may be contained in a larger surface-water basin based on topographic considerations, but contribute its runoff to ground water that surfaces in another surface-water basin.

HOW DRAINAGE AREAS ARE DETERMINED

Drainage basin boundaries and divides for the Florida District Office of the U.S. Geological Survey are determined in conformity to "Interagency Coordination of Drainage Area Data", Federal Interagency River Basin Committee, Notes on Hydrologic Activities- Bulletin No. 4, November 1951 which establishes both standards and methodology. U.S. Geological Survey 7 1/2-minute maps are the maps on which most drainage area delineations are made. When 7 1/2-minute topographic maps are not available, state base maps, aerial photographs, county maps, or state highway survey maps are used. As of 1979, the entire State of Florida is mapped on 1,047, U.S. Geological Survey topographic maps at a scale of 1:24,000 in the 7 1/2-minute series. These maps are considered to be accurate within 40 feet horizontally and one-half the contour interval vertically.

In order to determine a drainage area, a boundary is delineated along the natural ridge or the top of manmade features as shown on the map of the area. The effect of manmade drainage is taken into account. In some cases an on-the-ground investigation is made. The part of the area for each site on each map is planimeted, or measured by a mechanical or electronic device, which relates the area inside a closed line on the map to an area on the ground. Each map represents an area on the Earth's surface as determined on Smithsonian geological tables. When the total as planimeted is different from the area in the table, a constant is determined and each map area multiplied by it to balance the map.

After all the maps for a basin or site have been planimeted and the areas compared to and balanced against the area of the quadrangle, the areas for each site or basin are added together and a drainage area in square miles is tabulated.

The Florida District Office maintains a file of maps on which drainage areas are determined. In 1978, in cooperation with the Florida Department of Environmental Regulation, the District traced the entire file onto the latest 1:24,000-scale 7 1/2-minute topographic maps using a unified symbology. See figure 1 for an example of the basin map.

On these basin maps, the major basin boundaries are the heavy lines and generally correspond with the hydrologic unit lines. Basins for tributaries to the major streams and basins for coastal streams in coastal hydrologic units are outlined in the second heaviest lines; basins for tertiary streams are outlined in the third heaviest lines; and basins for other minor streams or landlocked lakes are outlined in the thinnest lines. Drainage areas for points along streams, such as gaging stations, lake outlets, or dams are shown by dashed lines. Block symbols with a number refer to locations where surface-water data have been or are being collected. Block symbols with a dot in the center indicate miscellaneous measurements at sites not operated on a periodic basis. Circles are sites where water-quality data were collected without discharge or lake elevation information.

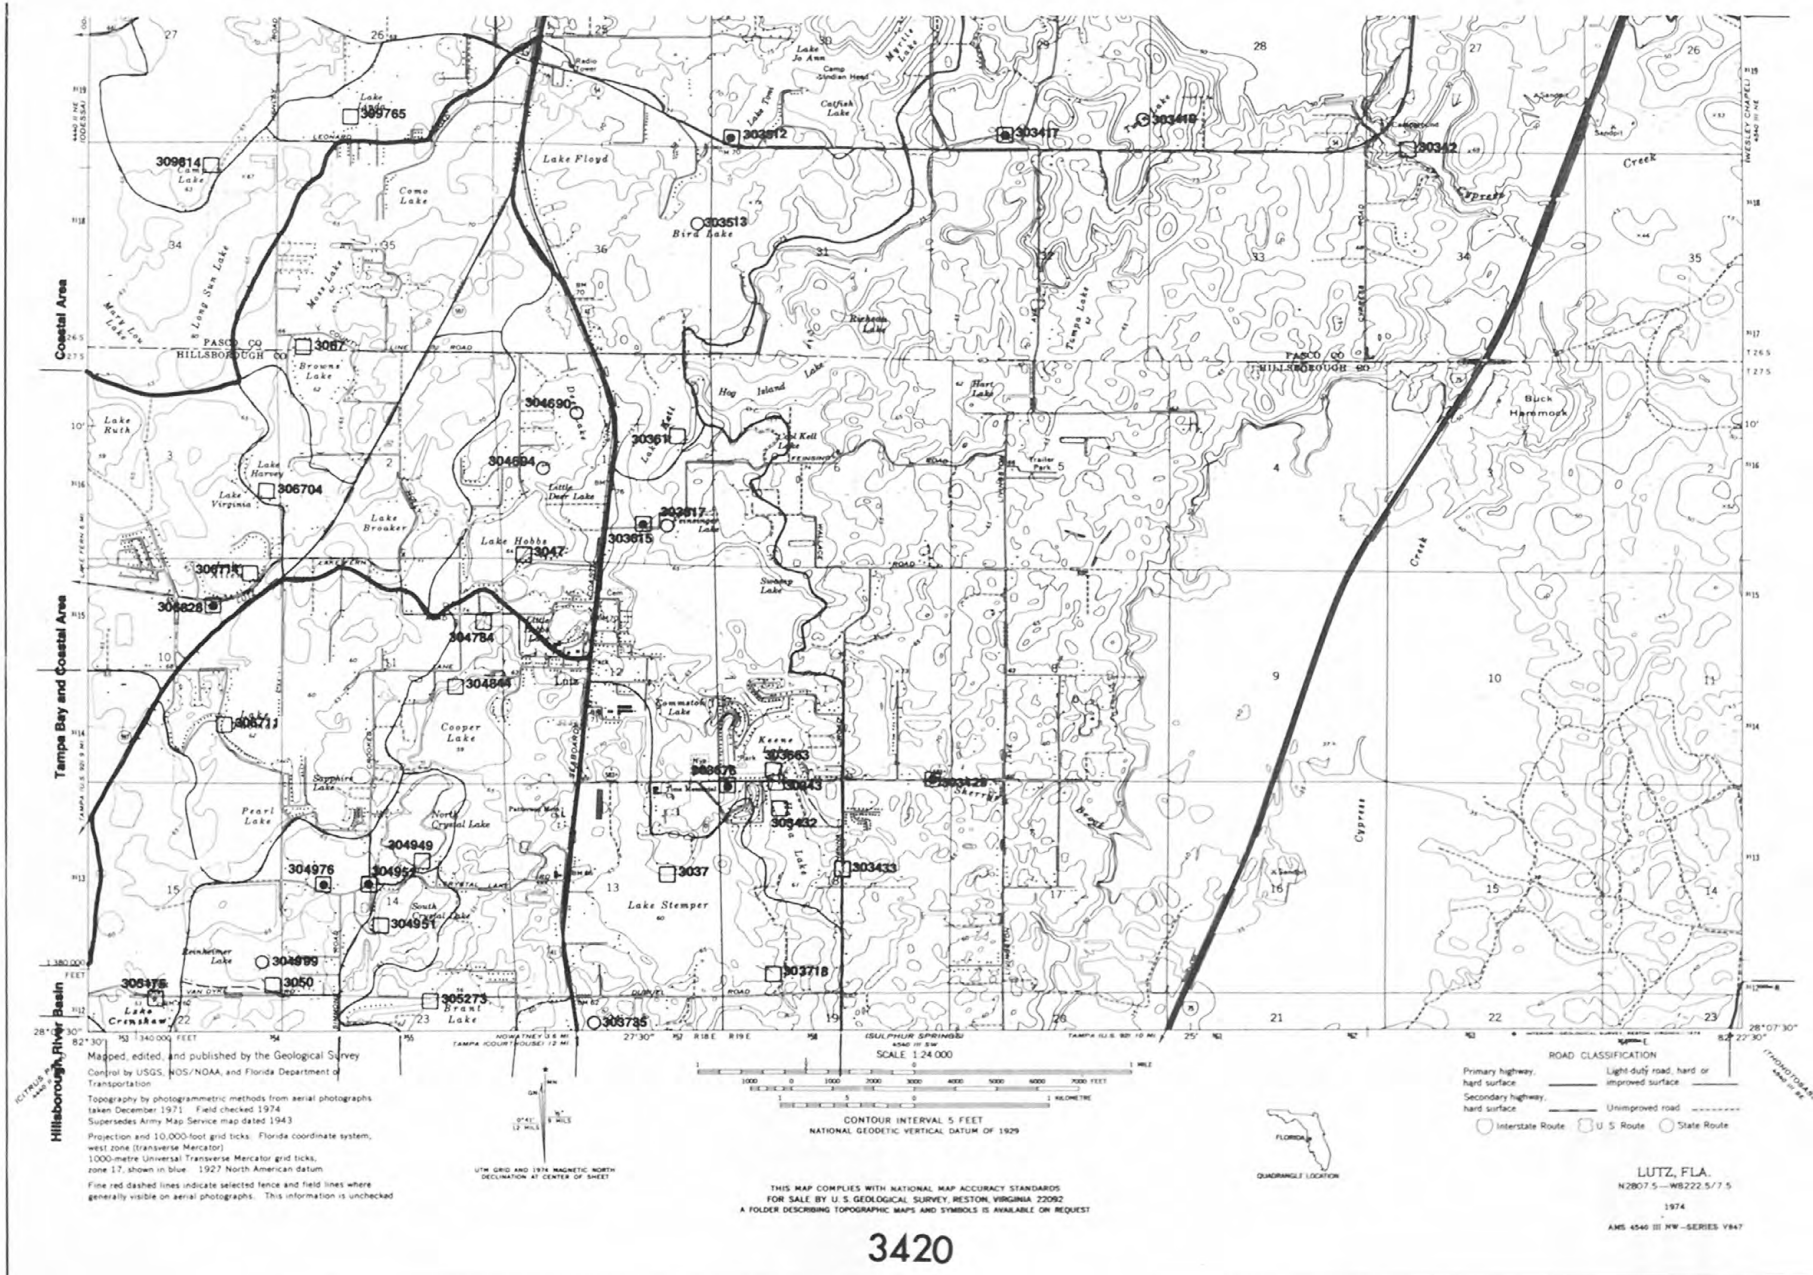

Figure 1. Part of a typical drainage basin map.

Ozalid copies of these maps are available from the U.S. Geological Survey, 325 John Knox Road, Suite F-240, Tallahassee, Florida 32303 for the cost of reproduction. An Index to Topographic Maps of Florida, issued by the Topographic Division of the U.S. Geological Survey, is contained in the back of this report. The name of each quadrangle is shown on the Index and is the only identification for ordering copies.
