

INTRODUCTION

This map shows the distribution of Pb, Zn, and Ag in the 80-mesh (<180 µm) fraction of stream sediments collected in the Golden Trout Wilderness during the summers of 1979 and 1980. Five grab samples of stream sediment were collected along 10 m of active stream channel and composited into a single sample. Sites were chosen on first- or second-order drainages, as defined by 1:62,500 topographic maps. All sites on second-order drainages were chosen 100 m below any first-order stream junction. Sample sites were selected at a density of one site per cell with the cell having an area of approximately one square mile (2.6 km²). A few cells may not contain a sample site because of various factors such as, lack of suitable stream drainages or extreme relief.

The 80-mesh (<180 µm) sediment fraction was pulverized at the laboratory and analyzed for 21 elements using an optical emission spectrophotometer, according to the method outlined by Grimes and Harrington (1968). A complete tabulation of the data for each sample collected in the Golden Trout Wilderness is given in Leach and others (1981). This report also presents a more detailed discussion of the sampling and analytical methods as well as statistical summaries of the data.

RESULTS

A histogram of the Pb concentrations in the stream-sediment samples is shown in Figure 1. The concentration ranges used to plot the Pb data were arbitrarily selected to approximate the top 5 percent, 25-75 percent, 75-95 percent, 95-99 percent, and the lower 25 percent. Because the spectroscopic concentrations are reported as geometric midpoints of ranges in concentrations, it is not possible to precisely divide the data into the desired percentiles. Therefore, the 5 symbols represent slightly different percentile ranges. Most of the samples contained concentrations of Zn and Ag below the detection limits; therefore, only those samples that contained detectable concentrations (including less-than-qualified concentrations) are plotted. To avoid overlap of the symbols, the Zn and Ag concentrations symbols were offset from the symbol for Pb which overlies the correct location of the sample.

We define the anomalous concentrations of Pb to include the 99-97 percentile (70 ppm) and the 98-100 percentile (100-300 ppm). All of the Zn and Ag concentrations plotted are considered anomalous. These concentration ranges for Zn and Ag would include the top 3 and 5 percent, respectively.

On the map, we have outlined the stream catchment area that may have contributed material for the anomalous metal concentrations. Four areas contain a significant number of samples with anomalous metal concentrations, and all have significant exposures of metamorphic roof pendant. The first area, south of the Mineral King District, and within the Little Kern River watershed, is characterized by anomalous concentrations of Pb, Zn, and Ag. This area is largely underlain by metamorphic rocks of the Mineral King roof pendant. The anomaly in the vicinity of Mountaineer and Alpine Creeks is underlain by the Mineral King roof pendant - granite of White Mountain, and granodiorite of Loggy Meadow, and is characterized by anomalous concentrations of Pb and Zn. The third anomalous area is located at the western edge of the study area, 2 mi northwest of Maggie Mountain. Stream sediments in this area are characterized by anomalous Pb concentrations; one sample contains anomalous Ag and Zn. The streams in this area drain an unnamed mountain underlain by the alkali of Maggie Mountain. The sites on the western edge of this area lie within the exposures of the metamorphic roof pendant.

The fourth area of anomalous metal concentrations is located on the eastern edge of the study area, between Braley Creek and upper South Fork of Ash Creek. The eastern third of this area contains anomalous concentrations of Ag in the stream sediments. This part of the anomalous area contains roof pendants of metamorphic rocks. In contrast, the western part of this anomalous zone is characterized by anomalous Pb concentrations and is underlain by the Cretaceous Whitney Granodiorite.

It is apparent that the highest concentration of Pb, Zn, and Ag in the stream sediments of the Golden Trout Wilderness correlate with metamorphic roof pendants and contact zones with the granitic intrusives. It is possible that the several isolated anomalous samples in various granitic rocks may be related to areas of abundant xenoliths.

EXPLANATION OF MAP SYMBOLS

SYMBOL	CONCENTRATION (ppm)	%FREQUENCY
+	not detected - 20	0 - 28
o	30	29 - 68
o	50	69 - 88
o	70	89 - 97
●	100-300	98 - 100
□	< 200-200	97 - 100
■	200-1000	
△	< 0.5-0.5	95 - 100
▲	0.5-10	

LIST OF MAP UNITS

SURFICIAL DEPOSITS

Qal	Alluvium
Qcl	Colluvium
Qm	Glacial Moraine
Qt	Talus
Qg	Gravel
Qls	Landslide Deposit
Qss	Gravel and Sand

VOLCANIC ROCKS

Qrl	Rhyolite of Long Canyon
Tb	Basalt
Trt	Rhyolite of Templeton Mountain

GRANITOID ROCKS

Km	Alaskite of Moses Mountain
Km	Alaskite of Maggie Mountain
Kap	Granodiorite of Quinn Peak
Kpc	Granodiorite of Beck's Canyon

GRANITOID ROCKS

Kwm	Granite of White Mountain
Ksc	Granodiorite of Sheep Creek
Kvf	Granodiorite of Volcano Falls
Ktr	Granodiorite of Tower Rock
Klm	Granodiorite of Loggy Meadow
Kcp	Alaskite of Coyote Pass
Klk	Granite of Little Kern Lake Creek
Khk	Alaskite of Hall's Hole
Jgf	Granite of Grasshopper Flat
Jm	Granodiorite of Doe Meadow
Juc	Granite of Window Cliffs

GRANITOID ROCKS

Klw	Granite of Little Whitney Meadow
Kw	Whitney Granodiorite
Kib	Intrusion Breccia of Timmons Peak
Kp	Paradise Granodiorite

GRANITOID ROCKS

Kcc	Granite of Carrall Creek
Krn	Granodiorite of Redneck Meadow
Kop	Alaskite of Olinda Peak
Jcu	Alaskite of Window Cliffs
Jwc	Granite of Window Cliffs (patterned area is a multi-phase)
Jkp	Alaskite of Kern Peak
Jm	Granodiorite of Schaeffer Meadow

IGNEOUS ROCKS

Kap	Aplite
Kfm	Mafic Plutonic Rock
KGp	Granodiorite

METAMORPHIC ROCKS

Mms	Metasedimentary Rocks
Mgm	Metamorphic Rocks, Undifferentiated
Mmv	Metavolcanic Rocks

- Boundary of Golden Trout Wilderness
- Geologic Contact
- Fault

MAP SHOWING DISTRIBUTION OF Pb, Zn, AND Ag IN STREAM SEDIMENTS FROM THE GOLDEN TROUT WILDERNESS, CALIFORNIA

By
D. L. Leach, R. J. Goldfarb, and J. A. Domenico
1981

Studies Related to Wilderness
The Wilderness Act (Public Law 88-577, Sept. 3, 1964) and related acts require the U.S. Geological Survey to survey certain areas on Federal lands to determine their mineral resource potential. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Golden Trout Wilderness, California.

Table 1. Statistical Summary of Pb Concentrations
(Calculations were made using qualified data by Cohen's method (1959). Details of the calculations are given in Leach and others, 1981.)

Detection Ratio*	0.99
Geometric Mean (ppm)	31
Geometric Deviation (ppm)	1.7
Expected Range for 95 percent of Data (ppm)	11-88
Arithmetic Mean (ppm)	36

*Number of uncensored values divided by total number of samples.
