GEOLOGICAL SURVEY

Chemical analyses of coal from the Krebs Group (Pennsylvanian), Arkoma basin, eastern Oklahoma

by

Ricky T. Hildebrand

Open-File Report 81-894

1981

Introduction

Coal-bearing rocks underlie 19 counties in eastern Oklahoma, an area of approximately 2,395 square miles. Recent estimates of bituminous coal resources in eastern Oklahoma (Friedman, 1975) show that 7.1 billion short tons of bituminous coal are present in beds 14 inches or more in thickness under less than 3,000 feet of overburden. Included as part of these identified resources is a coal reserve base of 1.3 billion short tons (Averitt, 1975). These are coal beds 28 inches or more in thickness to depths as great as 1,000 feet.

The coal resources of interest in this report lie within the boundaries of the Arkoma basin, a structural basin underlain by faulted and broadly folded Pennsylvanian strata. The counties within the Arkoma basin containing significant coal resources from which samples were collected are Haskell (1,513,681,000 short tons), Latimer (841,968,000 short tons), LeFlore (1,973,362,000 short tons), and Pittsburg (1,383,833,000 short tons) (Friedman, 1975). The locations of sample sites in the Arkoma basin are shown in figures 1 and 2.

Significant to any complete coal resource appraisal is an estimate of the chemical composition of the coal. Four somewhat overlapping reasons for obtaining comprehensive and precise chemical analyses of coal are as follows: (1) to help assess the environmental implications of coal mining and utilization, (2) to help determine the most suitable use of the coal, (3) to assess possible by-product recovery, and (4) to help interpret the geological and geochemical history of the coal-bearing rocks (Hatch and Swanson, 1977).

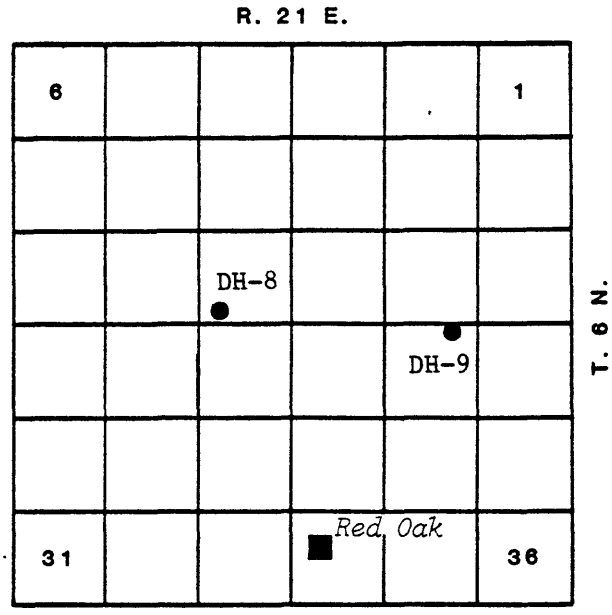
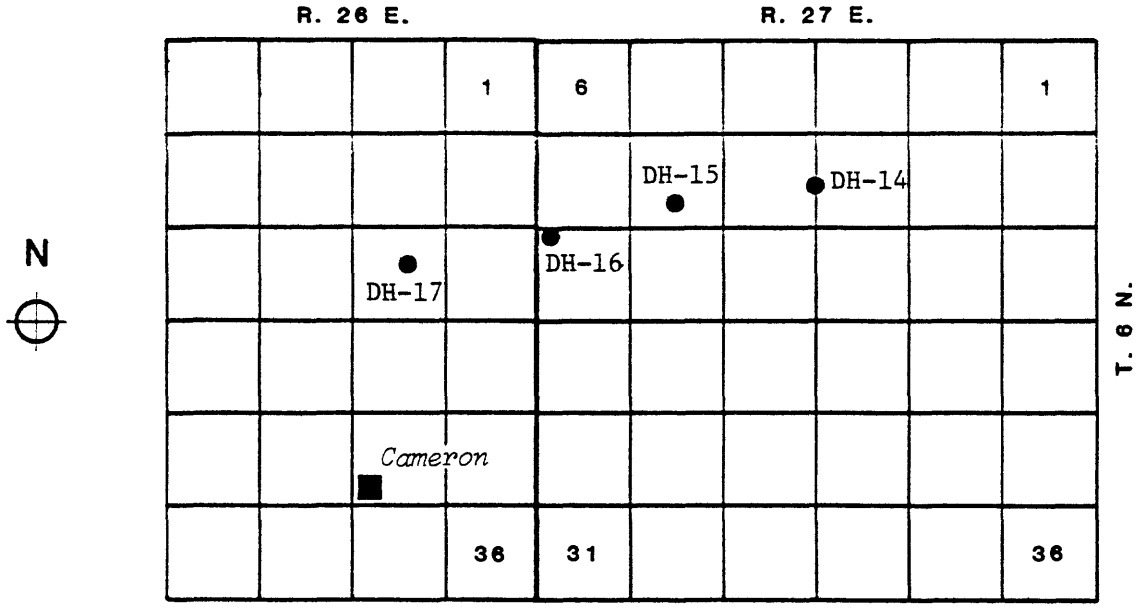
Locations of drill holes 2 & 3
Blocker 7.5' quad, Pittsburg Co.



Locations of drill holes 8 & 9
Red Oak 15' quad, Latimer Co.



Locations of drill holes 14 - 17
Hackett and Spiro 7.5' quads, LeFlore Co.

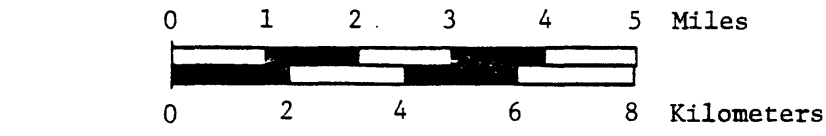


Figure 2.--Locations of sampled drill holes, Arkoma Basin EMRIA Program, eastern Oklahoma.

A total of 51 samples of coal were collected from the Arkoma basin, including 39 samples collected from several active mines by the Oklahoma Geological Survey (table 1) and 12 samples collected from eight EMRIA drill holes (table 2). These samples represent six principal coal beds in the Krebs Group of Middle Pennsylvanian (Des Moinesian) age. Figure 3 shows the general stratigraphy of formations and coal beds in the Krebs Group.

More detailed information on the general geology and stratigraphy of coal-bearing strata in eastern Oklahoma is included in Trumbull (1957), Johnson and others (1972), and Friedman (1975). Additional studies on trace elements in coal in the Arkoma basin and vicinity are included in Zubovic and others (1967), Boerngen and others (1975), and Swanson and others (1976).

Explanation of data and summary tables

Proximate and ultimate analyses, heat-of-combustion, air-dried-loss, forms-of-sulfur, free-swelling-index, and ash-fusion-temperature determinations for 30 single and composite coal samples from the Arkoma basin, eastern Oklahoma, are given in table 3. These analyses were provided by the Coal Analysis Section, Department of Energy (formerly U.S. Bureau of Mines), Pittsburgh, Pa. Analyses for ash content, contents of 36 major and minor oxides and trace elements in the laboratory ash (table 4), and analyses of seven trace elements in whole coal (table 5) for 51 coal samples from the Arkoma basin were provided by the U.S. Geological Survey in Denver, Colo. Table 6 contains the data listed in table 4 converted to a whole-coal basis and includes the whole-coal analyses listed in table 5. Twenty-two additional elements not listed in tables 4, 5, and 6 were looked for but not found in amounts greater than their lower limit of detection (table 7).

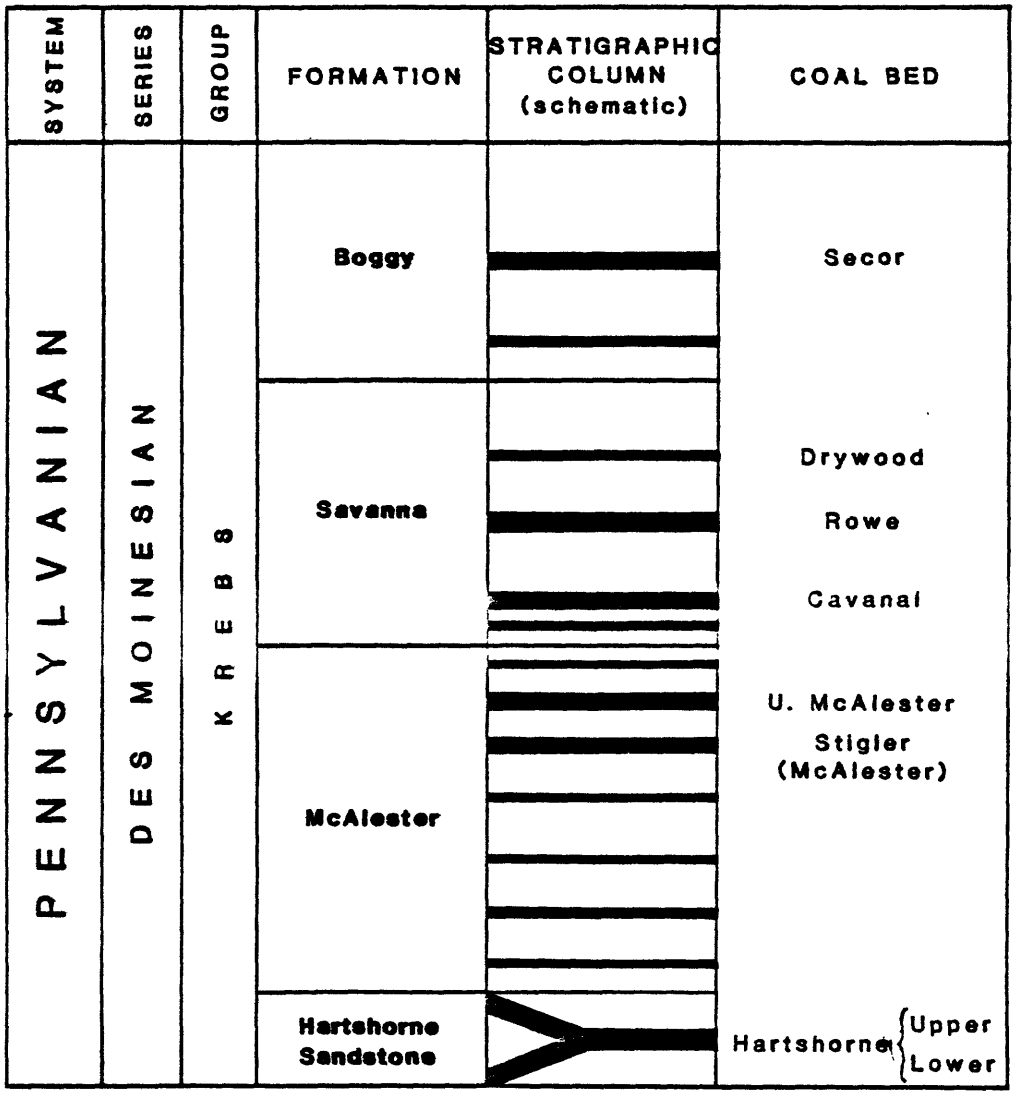

Figure 3.--Generalized stratigraphic column showing sequence of coal beds, Krebs Group, Arkoma basin, eastern Oklahoma (modified from Friedman, 1975).

Unweighted statistical summaries of the analytical data in tables 3, 4, and 6 are summarized in tables 8, 9, and 10. Data summaries for P_2O_5 content in ash, and Ag, Cd, Ce, Ge, La, Nd, P, and Th contents in whole coal are not included in tables 9 and 10 because these elements were detected in an insufficient number of samples to calculate meaningful statistics.

Most of the analytical procedures used by the U.S. Geological Survey are described in Swanson and Huffman (1976). Arsenic contents of samples summarized in this report have been determined by three different analytical methods: samples D176165 - D176854 were analyzed spectrophotometrically (lower detection limit 1.0 ppm); samples D179902 - D179910 were analyzed by the graphite furnace-atomic absorption method (lower detection limit 0.5 ppm); the remaining 11 samples were analyzed by instrumental neutron activation analysis (lower detection limit 0.1 ppm).

Antimony, selenium, and thorium contents of samples D176165 - D179910 were determined by the Rhodamine-B spectrophotometric method (lower detection limit 0.1 ppm), x-ray fluorescence analysis (lower detection limit 0.1 ppm), and delayed neutron activation analysis (lower detection limit 3.0 ppm), respectively. The remaining 11 samples were analyzed for antimony, selenium, and thorium by instrumental neutron activation analysis (lower detection limit 0.1 ppm).

To be consistent with the precision of the semiquantitative emission spectrographic technique, arithmetic and geometric means of elements determined by this method are reported as the midpoint of the enclosing six-step brackets. (See headnote of table 4 or Swanson and Huffman, 1976, p. 6, for an explanation of six-step brackets). The typical procedure for sample preparation and analysis used by the U.S. Geological Survey is shown in figure 4.

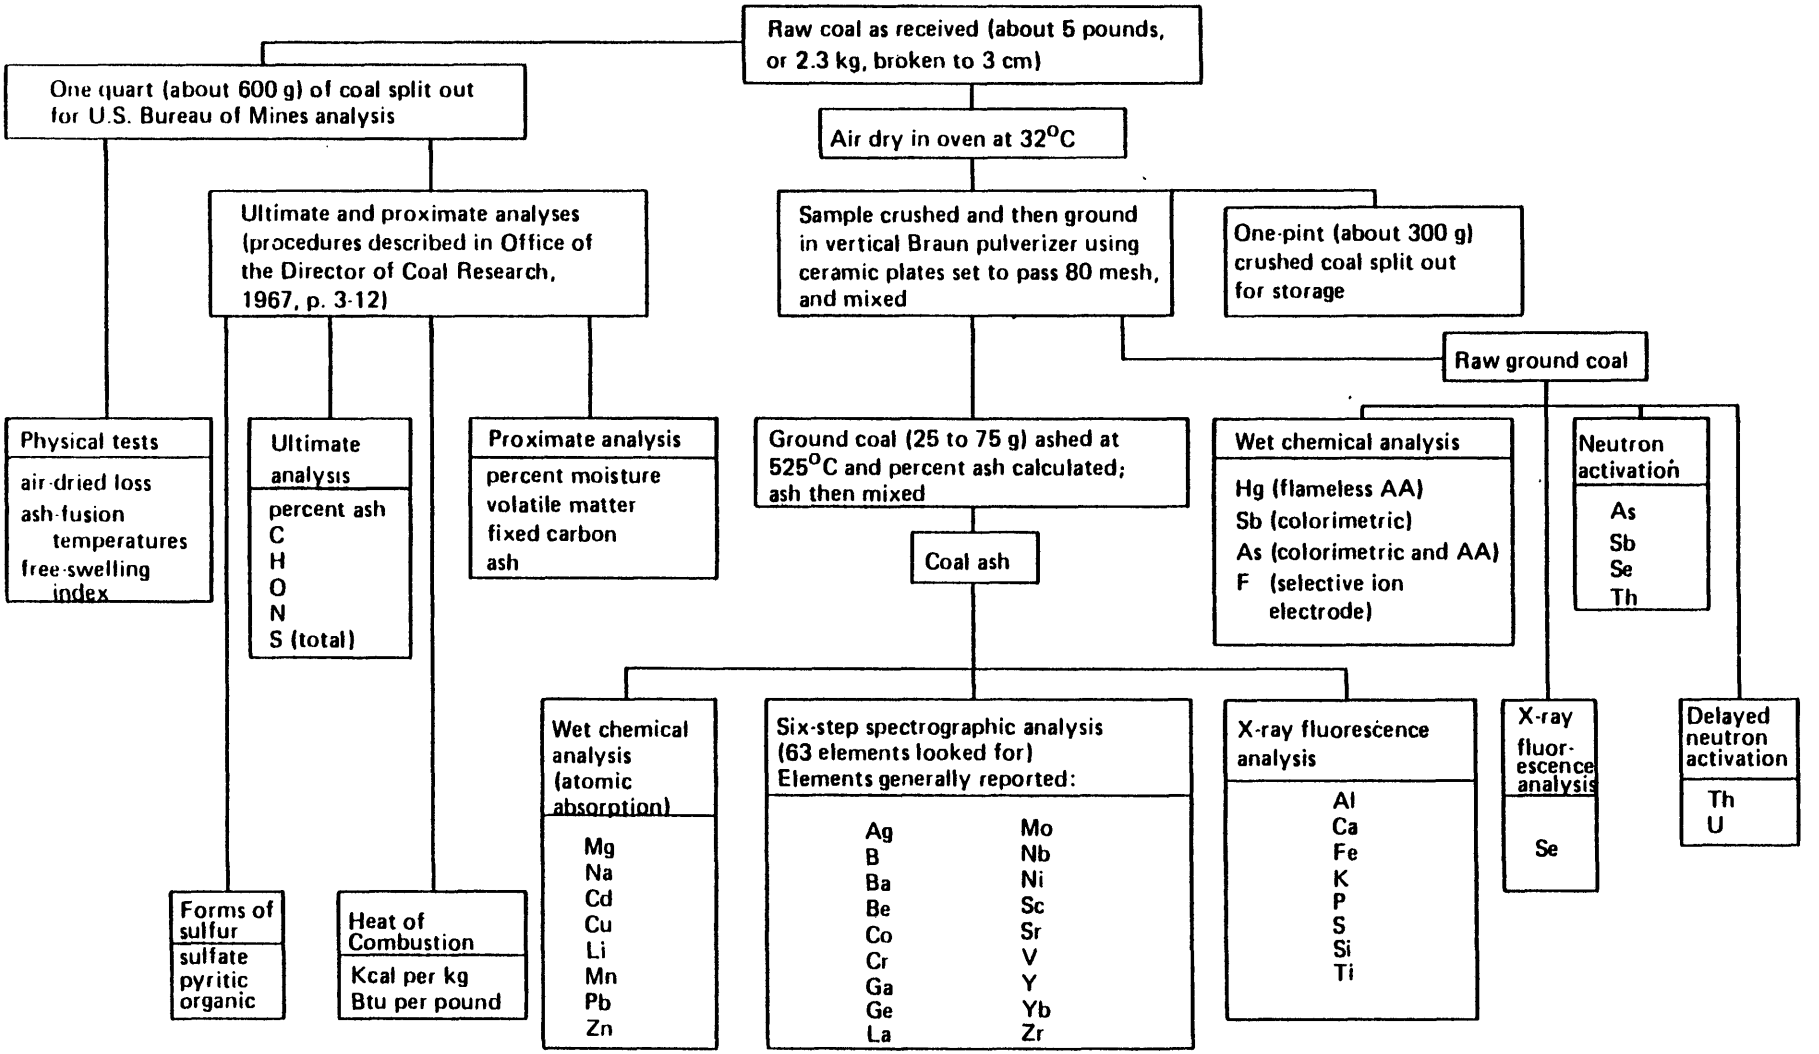

Figure 4.--Flow chart showing sequence of sample preparation and chemical analysis (modified from Swanson and Huffman, 1976).

Explanation of statistical terms used in summary tables

In this report the geometric mean (GM) is used as the estimate of the most probable concentration (mode). The GM is calculated by taking the logarithm of each analytical value, summing the logarithms, dividing the sum by the total number of values, and obtaining the antilogarithm of the result. The measure of scatter about the mode used here is the geometric deviation (GD), which is the antilog of the standard deviation of the logarithms of the analytical values. These statistics are used because the quantities of trace elements in natural distributions are normalized by statistically analyzing and summarizing trace-element data on a logarithmic basis.

If the frequency distributions are lognormal, the GM is the best estimate of the mode, and the estimated range of the central two-thirds of the observed distribution has a lower limit equal to GM/GD and an upper limit equal to GM x GD. The estimated range of the central 95 percent of the observed distribution has a lower limit equal to $GM/(GD)^2$ and an upper limit equal to GM x $(GD)^2$ (Connor and others, 1976).

Although the geometric mean is, in general, an adequate estimate of the most common analytical value, it is, nevertheless, a biased estimate of the arithmetic mean. The estimates of the arithmetic means listed in the summary tables are Sichel's t statistic (Miesch, 1967).

A common problem in statistical summaries of trace-element data arises when the element content of one or more samples is below the limit of analytical detection. This results in a "censored" distribution. Procedures developed by Cohen (1959) are used to compute biased estimates of the GM, GD, and arithmetic mean when the data are censored.

Discussion

The apparent ranks for 29 samples from the Arkoma basin were calculated using the data in table 3 and the formulae in ASTM designation D-388-77 (American Society for Testing and Materials, 1978). The heat of combustion (moist, mineral-matter free basis) for the samples from the Arkoma basin ranges from 14,260 Btu/lb (7,930 kcal/kg) to 15,620 Btu/lb (8,680 kcal/kg); the fixed carbon (dry, mineral-matter free basis) ranges from 55.9 percent to 81.9 percent. The distribution of apparent rank for the samples is as follows: high-volatile A bituminous coal--13 samples; medium-volatile coal--5 samples; and low-volatile bituminous coal--11 samples. The free-swelling index for the samples ranges from 1.0 to 9.0. Apparent rank and free-swelling index were not included for sample D223850 because of the high ash content.

Statistical comparisons, using the "t" and "f" tests (95-percent confidence) (Miller and Kahn, 1962), of the sample means and variances for the U.S. Department of Energy data for 30 samples from the Arkoma basin with 90 Interior Province coal samples (Swanson and others, 1976) show that the Arkoma basin samples collectively have significantly higher contents of fixed carbon, carbon, and nitrogen, a significantly higher heat of combustion, and significantly lower contents of moisture, volatile matter, hydrogen, oxygen, sulfur, and pyritic and organic sulfur. Contents of ash and sulfate sulfur are not significantly different.

Statistical comparisons of sample means and variances of coal ash and nine major and minor oxides in ash for 51 Arkoma basin samples with 155 Interior Province coal samples (Hatch and Swanson, 1977) show that the Arkoma basin samples collectively have a significantly lower ash content, significantly lower content of Fe_2O_3 in ash, and significantly higher contents of Al_2O_3, MgO, Na_2O, and K_2O in ash. Contents of SiO_2, CaO, TiO_2, and SO_3 in ash are not significantly different.

Statistical comparisons of sample means and variances of 34 elements (whole-coal basis) for 51 Arkoma basin samples with 155 Interior Province coal samples (Hatch and Swanson, 1977) show that the Arkoma basin samples collectively have significantly higher contents of Mg, Ba, Mo, Nb, and Sr, and significantly lower contents of Fe, B, Be, Co, Cu, N, Pb, Sb, Sc, Se, U, and Zn. Contents of Si, Al, Ca, Na, K, Ti, As, Cr, F, Ga, Hg, Li, Mn, V, Y, Yb, and Zr are not significantly different.

Differences in the oxide composition of coal ash and the element contents of coal result from differences in the total and relative amounts of the various minerals in the coal, and the total and relative amounts of organically bound elements. The chemical form and distribution of a given element are dependent on the geologic history of the coal bed. A partial listing of the geologic factors that influence element distributions includes chemical composition of original plants; amounts and compositions of various detrital, diagenetic, and epigenetic minerals; temperatures and pressures during burial; and extent of weathering. No evaluation of these factors has been made for any of the coal beds in the Arkoma basin.

Compared to coal from the Interior province (Swanson and others, 1976), coal in the Arkoma basin is generally characterized by low ash, low sulfur, high fixed carbon, and high heat content. The contents of trace elements, particularly Be, Pb, Sb, Se, and Zn, are generally low in coal from the Arkoma basin when compared collectively to coal from the Interior province (Hatch and Swanson, 1977).

Acknowledgments

Fundamental to this paper is the contribution of the team of chemical laboratory personnel in the U.S. Geological Survey under the direction of Claude Huffman, Jr.: James W. Baker, Ardith J. Bartel, Leon A. Bradley, Elaine L. Brandt, George T. Burrow, Nancy M. Conklin, James G. Crock, Celeste M. Ellis, Edward J. Fennelly, Johnnie M. Gardner, Patricia G. Guest, John C. Hamilton, Raymond G. Havens, Jay P. Hemming, Jesse O. Johnson, Roy J. Knight, Frederick E. Lichte, Barbara A. Keaten, Robert E. McGregor, Violet M. Merritt, Hugh T. Millard, Jr., Harriet G. Nieman, Ralph L. Nelms, Jeffry O'Kelley, Charles A. Ramsey, George O. Riddle, Gaylord D. Shipley, Joseph E. Taggart, Jr., James A. Thomas, Michele L. Tuttle, Richard E. Van Loenen, Robert B. Vaughn, Robin J. Vinnola, James S. Wahlberg, William J. Walz, Ralph J. White, and Robert J. Young. The invaluable contribution of the chemists in the Coal Analysis Section (Forrest E. Walker, Chemist-in-Charge (ret.) and John E. Puskas, Acting Chief), U.S. Department of Energy, Pittsburgh, Pa., is also gratefully appreciated.

Table 4.--Major- and minor-oxide and trace-element composition of the laboratory ash of 51 coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[Coal ashed at 525°C. L means less than the value shown; N, not detected; B, not determined. S after the element title indicates determinations by semiquantitative emission spectrography. The spectrographic results are to be identified with geometric brackets whose boundaries are part of the ascending series 0.12, 0.18, 0.26, 0.38, 0,56, 0.83, 1.2, etc., but reported as midpoints of the brackets, 0.1, 0.15, 0.2, 0.3, 0.5, 0.7, 1.0, etc.; precision of the spectrographic data is plus-or-minus one bracket at 68-percent or plus or minus two brackets at 95-percent confidence level]

Table 6.--Major-, minor-, and trace-element composition of 51 coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[Values are reported on a whole-coal basis. As, F, Hg, Sb, Se, Th, and U values are from direct determinations on air-dried (32°C) coal; all other values calculated from analyses of ash. S means analysis by semiquantitative emission spectroscopy. L, less than the value shown; N, not detected; B, not determined]

Table 7.--Elements looked for but not detected in coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[Approximate lower detection limits in ash, as determined by the six-step spectrographic method of the U.S. Geological Survey, are included for all elements]

Element name	Symbol	Lower limit of detection in ash (ppm)
Gold	Au	50
Bismuth	Bi	20
Dysprosium	Dy	100
Erbium	Er	100
Europium	Eu	200
Gadolinium	Gd	100
Hafnium	Hf	200
Holmium	Ho	50
Indium	In	20
Lutetium	Lu	70
Palladium	Pd	5
Praseodymium	Pr	200
Platinum	Pt	100
Rhenium	Re	100
Samarium	Sm	200
Tin	Sn	20
Tantalum	Ta	1,000
Terbium	Tb	700
Tellerium	Te	5,000
Thallium	Tl	100
Thulium	Tm	50
Tungsten	W	200

Table 8.--Arithmetic mean, observed range, geometric mean, and geometric deviation of proximate and ultimate analyses, and heat of combustion, forms of sulfur, and ash-fusion temperatures of 30 coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[All values are in percent except kcal/kg, Btu/lb, and ash-fusion temperatures, and are reported on the as-received basis. °F = (°C x 1.8) + 32; kcal/kg = 0.556 x (Btu/lb). Leaders (---) indicate no data. For comparison, geometric means for 90 Interior province coal samples (Swanson and others, 1976, table 16a) are included]

	Arithmetic mean	Observed range		Geometric mean	Geometric deviation	Interior province geometric deviation
		Minimum	Maximum			
Proximate and ultimate analyses						
Moisture	2.1	1.0	4.9	2.0	1.4	5.9
Volatile matter	26.3	13.9	38.9	25.1	1.4	30.9
Fixed carbon	59.1	28.0	75.5	57.4	1.3	46.3
Ash	13.2	2.6	56.0	10.3	2.0	10.7
Hydrogen	4.6	2.7	5.2	4.5	1.2	4.9
Carbon	72.8	33.2	85.7	71.6	1.2	64.3
Nitrogen	1.6	.7	2.1	1.6	1.2	1.2
Oxygen	5.5	2.2	9.6	5.3	1.4	10.7
Sulfur	2.5	.5	9.1	1.9	2.2	3.0
Heat of combustion						
Kcal/kg	7,170	3,130	8,320	7,050	1.2	6,360
Btu/lb	12,900	5,620	14,960	12,960	1.2	11,440
Forms of sulfur						
Sulfate	0.17	0.01	0.49	0.09	3.1	0.11
Pyritic	1.96	.02	7.26	.74	4.1	1.49
Organic	.75	.07	2.42	.59	2.0	1.05
Ash-fusion temperatures, °C						
Initial deformation	1,150	965	1,445	1,145	1.1	---
Softening temperature	1,200	1,040	1,500	1,195	1.1	---
Fluid temperature	1,250	1,075	1,540+	1,245	1.1	---

Table 9.--Arithmetic mean, observed range, geometric mean, and geometric deviation of ash content and contents of nine major and minor oxides in the laboratory ash of 51 coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[All samples were ashed at 525°C; all values except geometric deviation are in percent. For comparison, geometric means for 155 Interior province coal samples (Hatch and Swanson, 1977, table 4a) are included]

Oxide	Arithmetic mean	Observed range		Geometric mean	Geometric deviation	Interior province geometric mean
		Minimum	Maximum			
(Ash)	12.9	2.2	58.9	9.8	2.1	12.9
SiO_2	27	7.8	51	24	1.7	24
Al_2O_3	17	2.1	34	14	1.9	11
CaO	9.2	.31	22	5.4	2.8	5.4
MgO	2.5	.70	10.0	2.07	1.9	.81
Na_2O	.54	.14	1.70	.43	2.0	.27
K_2O	1.5	.20	3.2	1.3	1.8	.99
Fe_2O_3	26	3.6	60	20	2.0	26
TiO_2	.66	.11	1.4	.56	1.8	.54
SO_3	8.6	.38	17	5.9	2.4	4.8

Table 10.—Arithmetic mean, observed range, geometric mean, and geometric deviation of 34 elements in 51 coal samples from the Krebs Group, Arkoma basin, eastern Oklahoma

[All analyses are in percent or parts per million and are reported on a whole-coal basis. L, less than the value shown. For comparison, geometric means for 155 Interior province coal samples (Hatch and Swanson, 1977, table 4b) are included]

Element	Arithmetic mean	Observed range		Geometric mean	Geometric deviation	Interior province geometric mean
		Minimum	Maximum			
			Percent			
Si	1.8	0.15	14	1.1	2.7	1.4
