CONVERSION FACTORS

For use of those readers who may prefer to use metric (SI) units rather than inch-pound units, the conversion factors for the terms used in this report are listed below:

Multiply	By	To obtain
cubic feet (ft^3)	0.02832	cubic meters (m^3)
gallons (gal)	3.785	liters (L)
miles (mi)	1.609	kilometers (km)
square miles (mi^2)	2.590	square kilometers (km^2)
cubic feet per second (ft^3/s or cfs)	0.02832	cubic meters per second (m^3/s)
gallons per minute (gal/min)	0.06309	liters per second (L/s)

To assist those readers not familiar with scientific notations used in some of the graphs, the conversion factors are listed below:

A scientific notation of	Is equal to	A scientific notation of	Is equal to
10^5	100,000	10^1	10
10^4	10,000	10^0	1.0
10^3	1,000	10^{-1}	0.10
10^2	100	10^{-2}	0.01
		10^{-3}	0.001

GLOSSARY

Biochemical Oxygen Demand (BOD)--a measure of the quantity of dissolved oxygen, in milligrams per liter, necessary for the decomposition of organic matter by micro-organisms, such as bacteria.

Class III Waters--categorization, in State of Florida Rules, of water used for recreation, propagation, and management of fish and wildlife.

Cubic feet per second (ft^3/s or cfs)--the rate of discharge representing a volume of 1 cubic foot passing a given point in 1 second. A discharge rate of 1 ft^3/s is equivalent to 7.48 gallons per second or 448.8 gallons per minute.

Discharge--the volume of water (or more broadly, total fluids) that passes a given point within a given period of time.

Micrograms per liter (ug/L)--a unit expressing the concentration of chemical constituents in solution as weight (micrograms) of solute per unit volume (liter) of water. One thousand micrograms per liter is equivalent to one milligram per liter.

Milligrams per liter (mg/L)--a unit expressing the concentration of chemical constituents in solution. Milligrams per liter represents the weight of solute (in milligrams) per unit volume (one liter) of water.

Specific Conductance--a measure of the ability of a water to conduct an electrical current, expressed in micromhos per centimeter at 25°C. Specific conductance is related to the type and concentration of ions in solution and can be used for approximating the dissolved-solids concentration of the water. Commonly, the concentration of dissolved solids (in milligrams per liter) is about 65 percent of the specific conductance (in micromhos). This relation is not constant from stream to stream, and it may vary at the same point with a change in the composition of the water.

Total Organic Carbon (TOC)--a measure of the organically related carbonaceous content of water. It includes all natural and manmade organic compounds which are combustible at a temperature of 950°C.

QUALITY OF SURFACE WATER AT SELECTED SITES IN THE SUWANNEE RIVER BASIN, FLORIDA, 1980

By John E. Coffin

ABSTRACT

This report presents the results of analyses of water-quality samples collected from 14 surface-water sites in the Suwannee River basin in Florida from January through December 1980. The U.S. Geological Survey, in a cooperative investigative program with the Suwannee River Authority, has sampled a network of nine water-quality monitoring stations since 1968 to detect short-term and long-term changes in surface-water quality in the Suwannee River. Two additional stations, Camp Branch near Genoa and Rocky Creek near Houston, were established in October 1978. Three more stations have been included in this report. They are Deep Creek and Robinson Creek near Suwannee Valley, which originate in the Osceola National Forest, and Santa Fe River at Worthington Springs. The forest stations have been supported since April 1976 through a cooperative agreement with the U.S. Bureau of Land Management and the Worthington Springs station was established as a National Stream Quality Accounting Network (NASQAN) station in March 1979.

The analyses of samples collected routinely included: nutrients, total organic carbon, and 5-day biochemical oxygen demand, bimonthly; and trace metals, annually. The array of constituents sampled was expanded in October 1978 at three of the original nine stations to provide quality-of-water information for streams draining an industrial area: Rocky Creek near Belmont, Hunter Creek near Belmont, and Swift Creek at Facil. Data collected at these three sites now include: major chemical constituents, six times per year; radium-226, two times per year; and trace metals, one time per year. These constituents are determined in addition to nutrients, total organic carbon, and biochemical oxygen demand which continue to be analyzed six times per year.

All results of analyses of the water-quality samples collected from January through December 1980 remained within, or near, previously measured ranges and water-quality fluctuations were similar to those noted from data collected since 1971.

INTRODUCTION

The Suwannee River drains approximately 9,950 square miles of Georgia and Florida as it meanders southward from the Okefenokee Swamp and 202 river miles of Georgia and Florida to the Gulf of Mexico--a straight line distance in Florida of about 100 miles. The Withlacoochee, Alapaha, and Santa Fe Rivers are major tributaries to the Suwannee River (fig. 1). Numerous springs contribute to the flow of the Suwannee and its tributary streams. Nine springs are of first magnitude (average flows of at least 100 ft^3/s) with a total average discharge of 2,100 ft^3/s (Rosenau and others, 1977, p. 7). Streamflow records show that the 40-year average discharge of the Suwannee River at Wilcox is 10,580 ft^3/s. The maximum discharge of 84,700 ft^3/s occurred on April 14, 1948, and the minimum of 3,270 ft^3/s occurred on February 24, 1957. The Wilcox station, being the most downstream gaging site, indicates the total river discharge to the gulf. In water year 1980, the station recorded an average discharge of 10,760 ft^3/s, a maximum of 26,600 ft^3, and a minimum of 4,800 ft^3/s. These figures do not take into account the additional increase in discharge which occurs between Wilcox and the gulf.

The economy of the area is primarily agricultural, including dairy and truck farming. A large portion of the work force, however, is involved in other industries including construction, mining, manufacturing, and agribusiness.

The U.S. Geological Survey has been monitoring the water quality of streams in the Suwannee River basin since 1968 under a cooperative agreement between the Survey and the Suwannee River Authority. The jointly funded investigation is seeking to detect short-term and long-term changes in the quality of river water through extensive chemical and physical sampling and analysis. Hydrologic data are also collected at two gaging stations on creeks which originate in Osceola National Forest; these stations are supported with funds from the U.S. Bureau of Land Management and the Survey. Both creeks are generally representative of natural streamflow and water quality from a forested area of the Suwannee River basin. Another station, located on the Santa Fe River at Worthington Springs, was recently established as a NASQAN site (National Stream Quality Accounting Network). It is one of 29 stations in Florida that are Federally funded and designed to meet water-quality information needs of agencies involved in planning on a national or regional scale. These three stations are included in this report in order to provide the Authority with a wider possible water-quality base.

Eighteen stream gaging stations are used to monitor the flow of the Suwannee River and its tributaries in Florida. This report presents chemical and physical data collected from January through December 1980

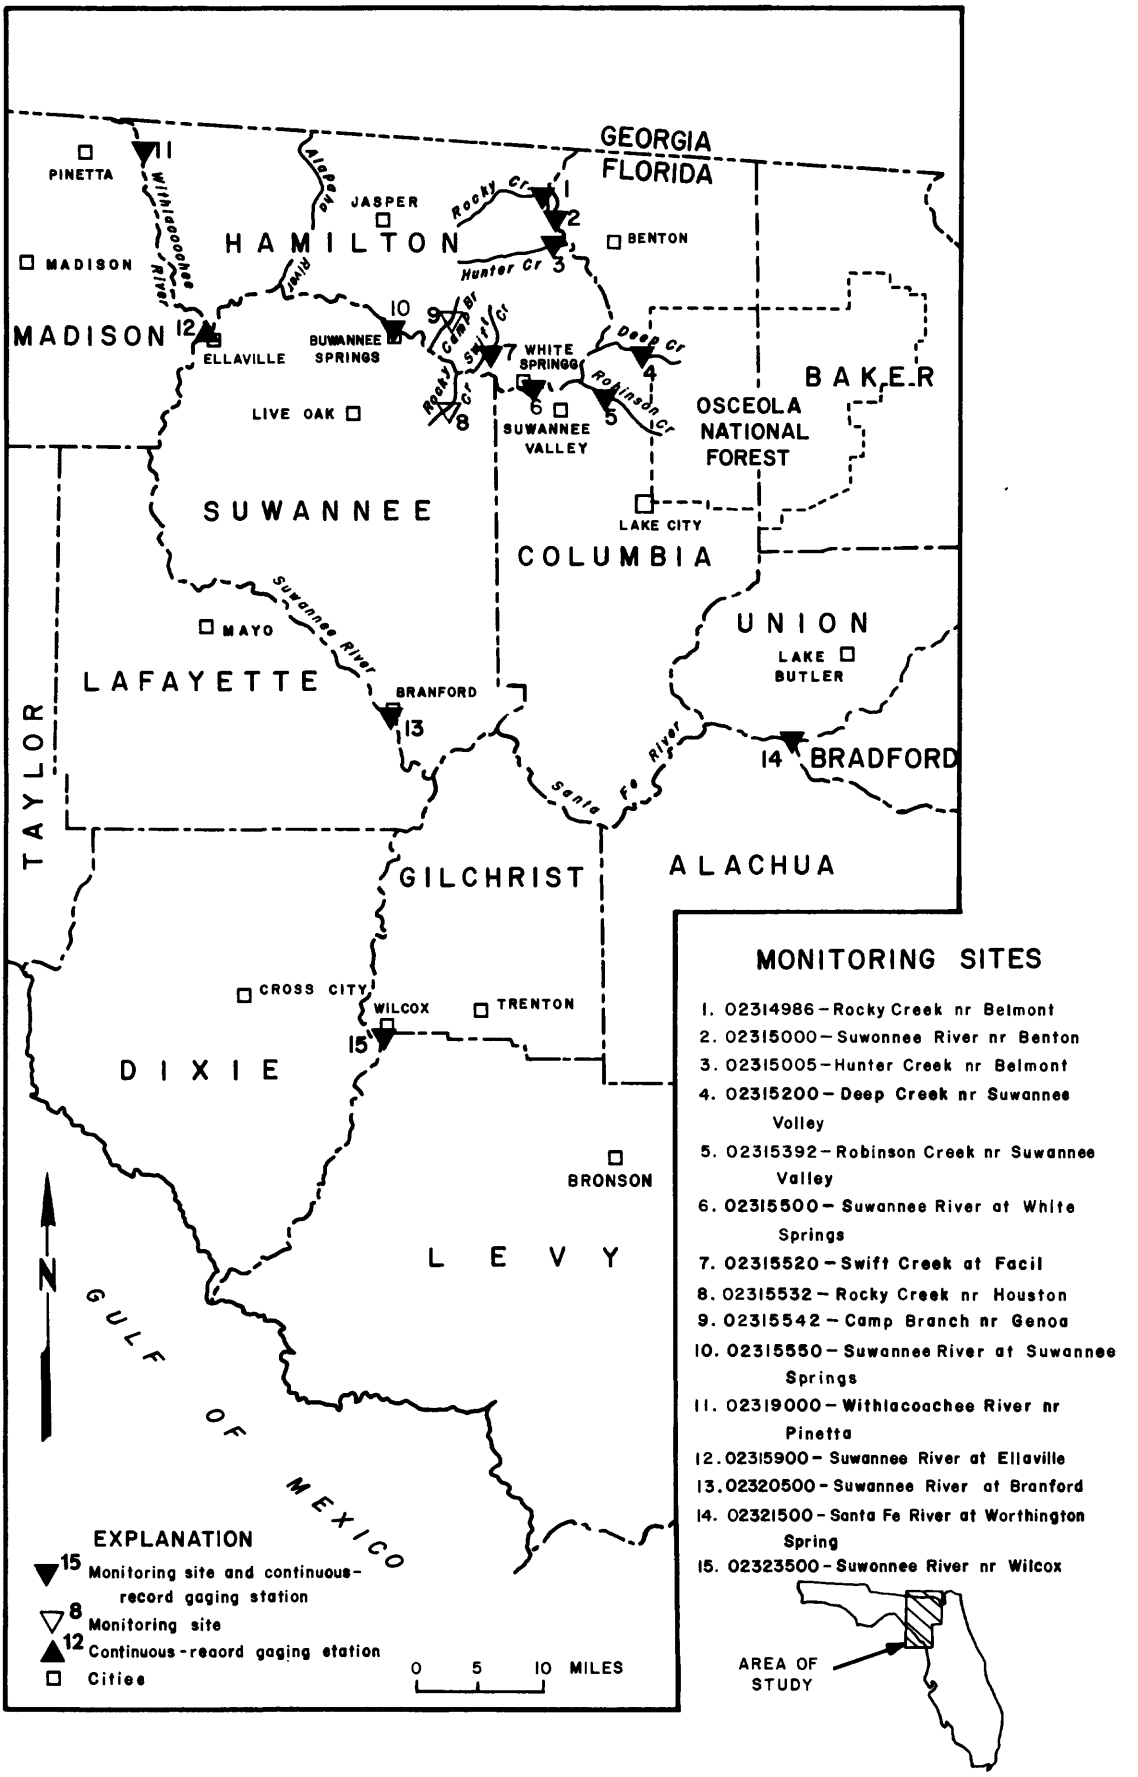

Figure 1.--Location of sampling stations in the Suwannee River basin, Florida.

at 14 of those stations. Selected data from previous years are included to show long-term trends of chemical and physical water-quality variables (Hull and others, 1980; Coffin, 1981). Water-quality samples are collected at five of six stations on the Suwannee and at nine of 12 stations on its tributaries.

STATION DESCRIPTIONS

The northernmost gaging station on a stream tributary to the Suwannee River in Florida is Rocky Creek near Belmont. The drainage area at this station is 50.0 square miles. Since August 1970, water-quality samples collected at this station have generally been analyzed for: nutrients, biochemical oxygen demand (BOD), and total organic carbon (TOC), bimonthly; and trace metals, annually. In October 1978, the sampling program was expanded to include major constituents (calcium, magnesium, bicarbonate, sulfate, sodium, chloride, potassium, and fluoride) six times per year and radium-226 two times per year. Discharge extremes are a maximum measured flow of 2,410 ft^3/s on April 6, 1973, and a minimum of no flow recorded many days during 1976-77. Located 1.4 miles upstream from the mouth of the creek, this site may be affected by backwater from the Suwannee River.

The northernmost gaging station on the main stem of the Suwannee River in Florida is Suwannee River near Benton. Located 6.4 river miles south of the Florida-Georgia State line and 196 miles upstream from the mouth of the river, it has a drainage area of 2,090 square miles in Georgia and Florida, which includes part of the watershed of the Okefenokee Swamp. Since October 1975, water-quality samples collected at this station have generally been analyzed for: nutrients, BOD, and TOC, bimonthly; and trace metals, annually. Prior to October 1975, this was an alternate site for making discharge measurements when the stage at White Springs was extremely high. Discharge extremes are a maximum measured flow of 27,000 ft^3/s on April 6, 1973, and a minimum recorded flow of 5.0 ft^3/s on August 9, 1977.

The station on Hunter Creek near Belmont is 0.8 miles upstream from the mouth of the creek and has a drainage area of 25.4 square miles. Since August 1971, water-quality samples collected at this station have generally been analyzed for: nutrients, BOD, and TOC, bimonthly; and trace metals, annually. In October 1978, the sampling program was expanded to include major constituents six times per year and radium-226 two times per year. This station was converted to a daily discharge site in January 1979. Discharge extremes are a maximum measured flow of 425 ft^3/s on June 26, 1972, and a minimum measured flow of 1.03 ft^3/s on June 6, 1977.

The station on Deep Creek near Suwannee Valley is 4.0 miles upstream from the mouth of the creek and has a drainage area of

88.6 square miles. Established in April 1976 as part of a study to determine the impact of potential phosphate mining in the Osceola National Forest, it is generally representative of natural streamflow and water quality from a forested area of the Suwannee River basin. Water-quality samples collected at this station have varied in frequency of collection. Sample analyses have generally included filtered and unfiltered nutrients, TOC, major constituents, trace metals, and radium-226. Discharge extremes are a maximum recorded flow of 961 ft^3/s on March 11, 1980, and a minimum recorded flow of 0.19 ft^3/s on May 25, 1977.

The station on Robinson Creek near Suwannee Valley is 3.4 miles upstream from the mouth of the creek and has a drainage area of 27.4 square miles. Also established in April 1976 as part of a study to determine the impact of potential phosphate mining in the Osceola National Forest, it is generally representative of natural streamflow and water quality from a forested area in the Suwannee River basin. Water-quality samples collected here have been for the same type of analysis and frequency of collection as those of Deep Creek. Discharge extremes are a maximum recorded discharge of 762 ft^3/s on March 10, 1980, and a minimum of no flow recorded many days in 1977.

Suwannee River at White Springs is 171 river miles upstream from the mouth of the river and has a drainage area of 2,430 square miles. Water-quality samples have generally been collected bimonthly for nutrient analysis and annually for trace metals. Discharge extremes are a maximum recorded flow of 38,100 ft^3/s on April 10, 1973, and a minimum recorded flow of 4.8 ft^3/s on November 15, 1931.

The station on Swift Creek at Facil is 2.8 miles upstream from the mouth of the creek and has a drainage area of 65.3 square miles. Since about 1965, flow has been partly regulated by control structures on the main channel, Altmans Bay canal, and an unnamed tributary. There is a possible interchange of water between Swift Creek, Hunter Creek, and Roaring Creek basins due to releases from the diked phosphate area encompassing parts of the three basins. Flow may contain some ground water pumped from the Floridan aquifer and used for phosphate industry processing. Since August 1969, water-quality sampling has generally included analyses for: nutrients, BOD, and TOC, bimonthly; and trace metals, annually. In October 1978, the sampling program was expanded to include analyses of major constituents six times per year and radium-226 two times per year. Discharge extremes are a maximum measured flow of 1,180 ft^3/s on June 27, 1972, and a minimum recorded flow of 1.6 ft^3/s on November 12, 1977.

The station on Rocky Creek near Houston is 2.5 miles upstream from the mouth of the creek and has a drainage area of 25.3 square miles. It

generally been analyzed for: nutrients, BOD, TOC, and major constituents six times per year; radium-226 twice per year; and trace metals once per year. Discharge extremes are a maximum measured flow of 56 ft^3/s on April 5, 1979, and a minimum of no flow observed on October 2 and December 4, 1978.

The station on Camp Branch near Genoa is 3.5 miles upstream from the mouth of the creek and has a drainage area of 6.1 square miles. It was established in October 1978 to expand data-collection activities in the area of Occidental Chemical Company. Water-quality samples have generally been analyzed for: nutrients, BOD, TOC, and major constituents six times per year; radium-226 twice per year; and trace metals once per year. Discharge extremes are a maximum measured flow of 10 ft^3/s on October 1, 1979, and minimum of no flow observed on October 2 and December 4, 1978.

Suwannee River at Suwannee Springs is 150 river miles upstream from the mouth of the river and has a drainage area of 2,630 square miles. Water-quality analyses generally include: nutrients, BOD, and TOC, bimonthly; and trace metals, annually. Discharge extremes are a maximum flow of 30,100 ft^3/s, determined indirectly from floodmarks, on April 12, 1973. A minimum discharge of 101 ft^3/s was recorded August 7-9, 1977.

The station on Withlacoochee River near Pinetta is 22 miles upstream from the mouth of the river and has a drainage area of approximately 2,120 square miles. Water-quality samples collected at this site generally are analyzed for: nutrients, BOD, and TOC, bimonthly; and trace metals, annually. Discharge extremes are a maximum flow of 79,400 ft^3/s, determined indirectly from floodmarks, on April 5, 1948. A minimum flow of 70 ft^3/s was recorded August 23, 1955.

The fourth downstream main-stem gaging station on the Suwannee River in Florida is near Ellaville. It is 200 feet downstream from the mouth of the Withlacoochee River and 127 river miles upstream from the mouth of the Suwannee River. It has a drainage area of 6,970 square miles. The maximum discharge, determined indirectly from floodmarks, was 95,300 ft^3/s on April 7-8, 1948. The minimum discharge of 882 ft^3/s was measured on July 17, 1955. Water-quality samples are not collected at this site because of incomplete mixing of Withlacoochee River water with that of the Suwannee River.

Suwannee River at Branford is 75 river miles upstream from the mouth of the river and has a drainage area of 7,880 square miles. Discharge extremes are a recorded maximum flow of 83,900 ft^3/s on April 11, 1948, and a minimum recorded flow of 1,530 ft^3/s on July 1-2, 1955. This station has been designated as a NASQAN station.

The station on Santa Fe River at Worthington Springs is 51 miles upstream from the mouth of the river and has a drainage area of 575 square miles. Discharge extremes are a maximum recorded flow of 20,000 ft^3/s on September 13, 1964, and a minimum recorded flow of 0.50 ft^3/s on June 24, 1955. This has also been designated as a NASQAN station. Data presented in the graphs and tables for this station start in March 1979 when NASQAN sampling was first begun.

The southernmost main-stem gaging station is Suwannee River near Wilcox. Located 33 miles upstream from the mouth of the river, it has a drainage area of 9,640 square miles. Water-quality samples collected generally are analyzed for: nutrients, BOD, TOC, bimonthly; and trace metals, annually. Discharge extremes are a maximum recorded flow of 84,700 ft^3/s on April 14, 1948, and a minimum recorded flow of 3,270 ft^3/s on February 24, 1957. Discharge is affected by Gulf of Mexico tides. This effect is minimal for discharges above 17,500 ft^3/s. Below this discharge tidal effect becomes more pronounced and discharge figures are adjusted according to magnitude of the tide effect.

SUMMARY OF DATA

Locations of the stations at which samples were collected are shown in figure 1. Chemical and physical water-quality data for the 1980 samplings are listed in tables 1 through 14. Table 15 lists maximum, minimum, and mean values for data available since October 1968. Table 16 is an inventory of the number of water-quality samples collected for each station for 21 categories. The number shown under each category represents the number of samples collected in a given year. Table 17 lists the recommended constituent limits for Class III waters for selected parameters. Table 18 briefly discusses the general significance of selected constituents and their possible sources. Selected parameter time graphs for each of the sampling stations are shown in figures 2 through 57. The time graphs show the general trend of the water-quality parameters since January 1971, or since the station was activated.

All results of the analyses of the water-quality samples collected during 1980 remained within, or near, previously measured ranges and water-quality fluctuations were similar to those noted from data collected since 1971.

Table 17.--State of Florida, Department of Environmental Regulation recommended constituent limits for Class III waters[1/]

Constituent	Limit, in mg/L, unless otherwise noted	Remarks
Cadmium	0.008	Predominantly freshwater
Chromium	0.05	After reasonable mixing in the receiving water
Coliform, total fecal, membrane filtered (colonies/100 mL)	2400	At any time
Copper	0.03	Predominantly freshwater
Dissolved oxygen	5.0	Freshwater aquatic life; lower limit
Fluoride	10.0	Surface waters: general criteria
Iron	1.0	Predominantly freshwater
Lead	0.03	Predominantly freshwater
Mercury	0.002	Predominantly freshwater
Nitrogen, ammonia	0.02	Un-ionized, freshwater aquatic life
pH, units	6.0–8.5	Predominantly freshwater
Specific conductance (micromhos/cm) at 25°C	500	Freshwater
Zinc	0.03	Predominantly freshwater

[1/] In 1979, the Suwannee River was designated as an Outstanding Florida Water. Recommended constituent limits for Outstanding Florida Waters are based on the ambient water-quality conditions. Because all of these ambient conditions have not yet been determined, Class III waters are used here for comparison purposes only.

Table 18.--General significance of dissolved mineral constituents and properties of water

[Modified from U.S. Geological Survey, 1979]

Constituent or property	Source or cause	General significance
Alkalinity	Caused primarily by bicarbonate, carbonate, and hydroxide. Other weak acid radicals like borate, phosphate, and silicate may contribute to alkalinity.	Ability of water to neutralize strong acid. High alkalinity itself not detrimental but usually associated with high pH, hardness, and dissolved solids which can be detrimental.
Aluminum (Al)	Usually present only in negligible quantities in natural waters except where the waters have been in contact with the more soluble rocks of high aluminum content. Acid waters often contain large amounts.	May be troublesome in feed waters forming scale on boiler tubes. High concentrations usually indicate the presence of acid mine drainage or industrial waste.
Arsenic (As)	Natural arsenic-bearing minerals. Found in some ground waters, in wastes from industry and mining activity, and residues from some insecticides and herbicides.	The U.S. Environmental Protection Agency, (1975) gives a limit of 50 ug/L for potable waters. Lethal dose for animals is believed to be about 20 milligrams per animal pound. Small concentrations in drinking water can accumulate in man and other animals until lethal dosage is reached.
Bicarbonate (HCO_3) and Carbonate (CO_3)	Produced by reaction of atmospheric carbon dioxide with water. Dissolved from carbonate rocks such as limestone and dolomite.	Bicarbonate and carbonate produce alkalinity. Bicarbonates of calcium and magnesium decompose in steam boilers and hot water facilities to precipitate as scale and release corrosive carbon dioxide gas. In combination with calcium and magnesium cause carbonate hardness.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Cadmium (Cd)	Found in wastes from pigment works, textile printing, lead mines, and chemical industries.	The results of animal studies suggest that very small amounts of cadmium can produce nephrotoxic and cardiovascular effects. The reproductive organs of animals are specifically affected after parenteral administration of very small amounts of cadmium salts. The U.S. Environmental Protection Agency (1975) states that cadmium in excess of 10 ug/L is cause for rejection of the water supply. Cadmium is also toxic to fish and aquatic life in varying concentrations.
Calcium (Ca) and Magnesium (Mg)	Dissolved from practically all soils and rocks, but especially from limestone, dolomite, and gypsum. Calcium and magnesium are found in large quantities in some brines. Magnesium is present in large quantities in seawater.	Causes most of the hardness and scale-forming properties of water; consumes soap (see hardness). Waters low in calcium and magnesium are desired in electroplating, tanning, dyeing, and in textile manufacturing.
Chloride (Cl)	Dissolved from rocks and soils. Present in sewage and found in large amounts in ancient brines, seawater, and industrial brines.	About 300 mg/L in combination with sodium gives salty taste to water. Increases the corrosiveness of water. The U.S. Environmental Protection Agency (1977) recommends that the chloride content should not exceed 250 mg/L.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Chromium (Cr)	Few if any waters contain chromium from natural sources. Natural waters probably contain only traces of chromium as a cation unless the pH is very low. When chromium is present in water, it is usually the result of pollution by industrial wastes such as metal pickling, plating, manufacturing of paints, dyes, explosives, ceramics, paper, glass, and photography processing.	The U.S. Environmental Protection Agency (1975) limits the maximum concentration of hexavalent chromium to 50 ug/L. Toxicity to aquatic life varies widely with the species, temperature, pH, and other factors.
Cobalt (Co)	Cobalt occurs in nature in the minerals smaltite $(Co,Ni)As_2$, and cobaltite, (CoAsS). Alluvial deposits soils derived from shales often contain cobalt in the form of phosphate or sulfate, but other soil types may be markedly deficient in cobalt in any form. Biological activity may aid in the solution of small amounts of cobalt. May also be present in industrial wastes especially those from manufacture of ceramics, inks, electric heating units, and cobalt pigments.	Usually suggests pollution. Relatively low toxicity to man. Fish and aquatic life tolerance varies widely and from less than 3 mg/L to more than 10 mg/L. Essential in trace quantities for plant growth.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Color	Yellow-to-brown color of some water is usually caused by organic matter extracted from leaves, roots, and other organic substances. Objectionable color in water also results from industrial wastes and sewage.	Water for domestic and some industrial uses should be free from perceptible color. The U.S. Environmental Protection Agency (1977) proposes a limit of 15 PtCo units. Color in water is objectionable in food and beverage processing and many manufacturing processes. Limits light penetration in water, thus preventing growth of some organisms.
Copper (Cu)	Copper is a fairly common trace constituent of natural water. Small amounts may be introduced into water by solution of copper and brass water pipes and other copper-bearing equipment in contact with the water or from copper salts added to control algae in open reservoirs. Copper salts such as the sulfate and chloride are highly soluble in waters with a low pH but in water of normal alkalinity the salts hydrolyze and copper may be precipitated. In the normal pH range of natural water containing carbon dioxide, the copper might be precipitated as carbonate.	Copper imparts a disagreeable metallic taste to water. As little as 1.5 mg/L can usually be detected, and 5 mg/L can render the water unpalatable. Copper is not considered to be a cumulative systemic poison like arsenic, lead, and mercury; most copper ingested is excreted by the body and very little is retained. The pathological effects of copper are controversial, but it is generally believed very unlikely that humans could unknowingly ingest the toxic quantities from palatable drinking water. The U.S. Environmental Protection Agency (1977) recommends that copper should not exceed 1 mg/L in drinking and culinary water. Copper is essential in trace amounts for plant growth but becomes toxic in large amounts.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Dissolved Oxygen (DO)	Dissolved in water from air and from oxygen given off in the process of photosynthesis by aquatic plants.	Dissolved oxygen increases the palatability of water. The amount necessary to support fish life varies with species and age, with temperature, and concentration of other constituents in the water. Under average stream conditions, 5 mg/L is usually necessary to maintain a varied fish fauna in good condition. For many industrial uses, zero dissolved oxygen is desirable to inhibit corrosion.
Dissolved solids	Chiefly mineral constituents dissolved from weathering of rocks and soils.	The U.S. Environmental Protection Agency (1977b) recommends that the dissolved solids should not exceed 500 mg/L, however, 1,000 mg/L is permitted under certain circumstances. Waters containing more than 1,000 mg/L of dissolved solids are unsuitable for many purposes. The Geological Survey classifies the degree of salinity of water as follows: Dissolved solids (mg/L): less than 1,000, nonsaline; 1,000 to 3,000, slightly saline; 3,000 to 10,000, moderately saline; 10,000 to 35,000, very saline; more than 35,000, brine.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Fluoride (F)	Dissolved in small to minute quantities from most rocks and soils. Enters many waters from fluoridation of municipal supplies.	Fluoride in drinking water reduces the incidence of tooth decay when the water is consumed during the period of enamel calcification. However, it may cause mottling of the teeth depending on the concentration of fluoride, the age of the child, amount of drinking water consumed, and susceptibility of the individual (Maier, 1950).
Hardness (as $CaCO_3$)	In most waters, nearly all the hardness is due to calcium and magnesium. All of the metallic cations other than the alkali metals also cause hardness.	Consumes soap before a lather will form. Deposits soap curd on bathtubs. Hard water forms scale in boilers, water heaters, and pipes. Hardness equivalent to the bicarbonate and carbonate is called carbonate hardness. Any hardness in excess of this is called non-carbonate hardness. Waters of hardness up to 60 mg/L are considered soft; 60 to 120 mg/L, moderately hard; 120 to 180 mg/L, hard; more than 180 mg/L, very hard.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Iron (Fe)	Iron is dissolved from many rocks and soils. On exposure to air, normal basic waters that contain more than 1 mg/L of iron soon become turbid with the insoluble reddish ferric compounds produced by oxidation. Surface waters, therefore, seldom contain as much as 1 mg/L of dissolved iron, although some acid waters carry large quantities of iron in solution.	On exposure to air, iron in ground water oxidizes to reddishbrown sediment. More than about 300 ug/L may stain laundry and utensils reddishbrown. Objectionable for food processing, textile processing, beverages, ice manufacture, brewing and other processes. The U.S. Environmental Protection Agency (1977), for esthetic reasons, recommends a limit of 300 ug/L. Larger quantities cause unpleasant taste and favor growth of iron bacteria.
Lead (Pb)	Lead seldom occurs in most natural waters, but industrial mine and smelter effluents may contain relatively large amounts of lead which contaminates the streams. Also, atmospheric contamination which is produced from several types of engine exhausts has considerably increased the availability of this element for solution in rainfall, resulting in contamination of lead in streams (Hem, 1970).	The U.S. Environmental Protection Agency (1975) states that lead shall not exceed 50 ug/L in drinking and culinary water on carriers subject to Federal quarantine regulations. Maximum safe concentrations for animal watering is reported to be 500 ug/L. Toxicity of lead to fish decreases with increasing water hardness.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Manganese (Mn)	Dissolved from some rocks and soils. Not as common as iron. Large quantities often associated with high iron content and with acid waters.	Same objectionable features as iron. Causes dark brown or black stain. The U.S. Environmental Protection Agency (1977) proposes that manganese should not exceed 0.05 mg/L.
Nickel (Ni)	Chiefly from metal-plating works, manufacturing of ceramic colors, and inks.	Presence of nickel in water may suggest pollution. Federal drinking water standards do not place a limit on nickel. In the Soviet Union the maximum permissible concentration is 1.0 mg/L (Kirkor, 1951).
Ammonia Nitrogen (NH_4, as N)	Includes nitrogen in the form of NH_3 and NH_4^+. Found in many waters but usually only in trace amounts. Waters from hot springs may contain high concentrations. Found also in waters polluted with sewage and other organic waste.	Usually indicates organic pollution. Toxicity to fish depends on the pH of the water; 2.5 mg/L ammonia nitrogen can be harmful in the 7.4 to 8.5 pH range (Ellis and others, 1948). Ammonium salts are destructive to concrete made from portland cement.
Organic Nitrogen (N)	Amino acids, proteins, and polypeptides. Derived from living organisms and their life processes and from wastes and sewage.	Sometimes indicates pollution. Increases nutrient content of water through decomposition and composition of other nitrogen forms.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Nitrate Nitrogen (NO_3, as N)	Decaying organic matter, sewage, fertilizers, and nitrates in soil.	Concentrations much greater than the local average may suggest pollution. The U.S. Environmental Protection Agency (1975) established a 10 mg/L maximum contamination level for Nitrate Nitrogen. More than about 10 mg/L of nitrate (N) may cause a type of methemoglobinemia in infants, sometimes fatal. Water of high nitrate content should not be used in baby feeding (Maxcy, 1950). Nitrate has shown to be helpful in reducing intercrystalline cracking of boiler steel. It encourages growth of algae and other organisms which produce undesirable tastes and odors.
Nitrite Nitrogen (NO_2, as N)	Unstable in the presence of oxygen and is present in only small amounts in most waters. Found in sewage and other organic wastes.	Presence of nitrite is usually an indication of recent organic pollution. Undesirable in waters for some dyeing and brewing processes.
Total Kjeldahl Nitrogen (N)	Includes ammonia nitrogen and organic nitrogen.	See organic and ammonia nitrogen.
Total Nitrogen (N)	All forms of nitrogen--inorganic and organic.	See ammonia nitrogen, nitrite, nitrate, and organic.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Hydrogen ion concentration (pH)	Hydrogen ions derived from ionization of weak and strong acids. Hydrogen on concentration is expressed in terms of pH where pH = log (H+). Acid generating salts and dissolved gases such as SO_2 and CO_2 increase the number of hydrogen ions. Carbonates, bicarbonates, hydroxides, phosphates, silicates, and borates reduce the number of hydrogen ions.	pH ranges between 0 and 14. A pH of 7.0 indicates solution having equal numbers of hydrogen and hydroxide ions. pH higher than 7.0 denotes predominance of hydroxide ions; values lower than 7.0 indicate predominance of hydrogen ions. Corrosiveness of water generally increases with decreasing pH. However, excessively alkaline waters may also attack metals. A pH range of 6.5-8.5 is recommended by the U.S. Environmental Protection Agency (1977).
Strontium (Sr)	Dissolved from rocks and soils. Found in seawater and many brines. Present in waters of local areas where strontium minerals such as celestite and strontianite are present.	Naturally occurring strontium is similar chemically to calcium and only adds to the hardness of water. Radioactive isotopes of strontium, as from nuclear bomb fallout, can be harmful. These isotopes can be detected by radiometric measurements.
Sulfate (SO_4)	Dissolved from rocks and soils containing gypsum, iron sulfides, and other sulfur compounds. Usually present in mine waters and in some industrial waters.	Sulfate in water containing calcium forms hard scale in steam boilers. In large amounts, sulfate in combination with other ions gives bitter taste to water. Some calcium sulfate is considered beneficial in the brewing process. The U.S. Environmental Protection Agency (1977) recommends that the sulfate content should not exceed 250 mg/L.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Temperature	Solar energy, thermal pollution from waste outfalls and heat from Earth's core.	Affects usefulness of water for many purposes. For most uses, a water of uniformly low temperature is desired. Shallow wells show some seasonal fluctuations in water temperature. Ground waters from moderate depths usually are nearly constant in temperature, which is near the mean annual air temperature of the area. In very deep wells, the water temperature generally increases on the average about 1°C with each 100foot increment of depth. Seasonal fluctuations in temperatures of surface waters are comparatively large, depending on the depth of water, but do not reach the extremes of air temperature.
Turbidity	Colloidal suspensions of sediment, precipitates, and other small particles.	The U.S. Environmental Protection Agency (1975) has established a maximum contaminant level as a monthly average of one nephelometric turbidity unit (NTU) [or 5 turbidity units (NTU) with state approval, provided it does not interfere with disinfection, maintenance of chlorine residual, or bacteriological testing]. Interferes with light penetration and limits growth of organisms. Also directly lethal to some life forms.

Table 18.--General significance of dissolved mineral constituents and properties of water--Continued

Constituent or property	Source or cause	General significance
Zinc (Zn)	Dissolved from some rocks and soils. Found in high concentrations in some mine waters having a low pH. Zinc is used in many commercial products and industrial wastes may contain large amounts. May be derived from zinc plated or galvanized metal products.	Large concentrations may be toxic to aquatic plants and animals. Zinc may have such a toxic action on purifying bacterial flora of streams as to present serious sewage pollution problems. Zinc is an essential and beneficial element in human metablism. The U.S. Environmental Protection Agency (1977) recommends that zinc should not exceed 5,000 ug/L (5 mg/L) in drinking water.
