UNITED STATES DEPARTMENT OF THE INTERIOR

GEOLOGICAL SURVEY

GEOCHEMICAL DATA FOR THE SIERRA ANCHA WILDERNESS AND SALOME AND CHERRY CREEK RARE II AREAS, ARIZONA

By

H. N. Barton, P. K. Theobald, and R. B. Tripp

Open-File Report 82-878

1982

STUDIES RELATED TO WILDERNESS

The Wilderness Act (Public Law 88-577, September 3, 1964) and related acts require the U.S. Geological Survey and the U.S. Bureau of Mines to survey certain areas on Federal lands to determine their mineral resource potential. Results must be made available to the public and be submitted to the President and the Congress. This report presents the results of a geochemical survey of the Sierra Ancha Wilderness and Salome and Cherry Creek RARE II areas.

INTRODUCTION

A geochemical reconnaissance study was made in April and May, 1978, as part of a study of the Sierra Ancha Wilderness and Salome and Cherry Creek RARE II areas by the U.S. Geological Survey and U.S. Bureau of Mines. Interpretive maps describe the geology, Berquist and others (1981); mining, Light (1981); geochemistry, Barton and others (1980), Negri and others (1980), Tripp and others (1980); and geophysics, Duval and Pitkin (1981).

Presented herein is a description of the techniques used for collecting and analyzing the geochemical samples; and the chemical analysis data.

The location of the Sierra Ancha Wilderness and adjacent RARE II areas is shown in Figure 1. Boundaries of the areas are shown in Figure 2.

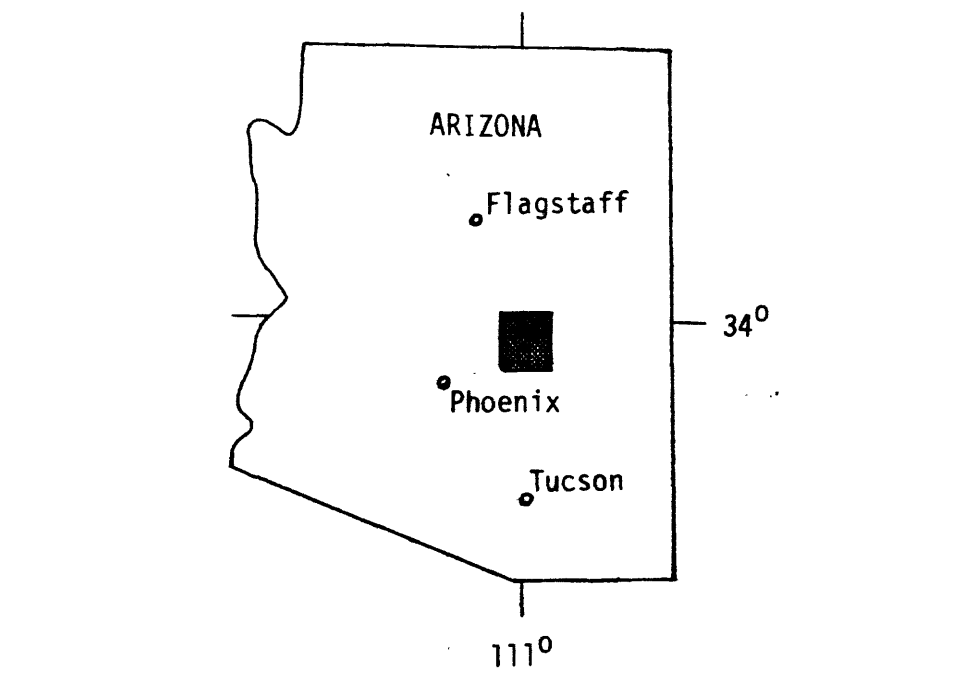

Figure 1.--Index map of study area.

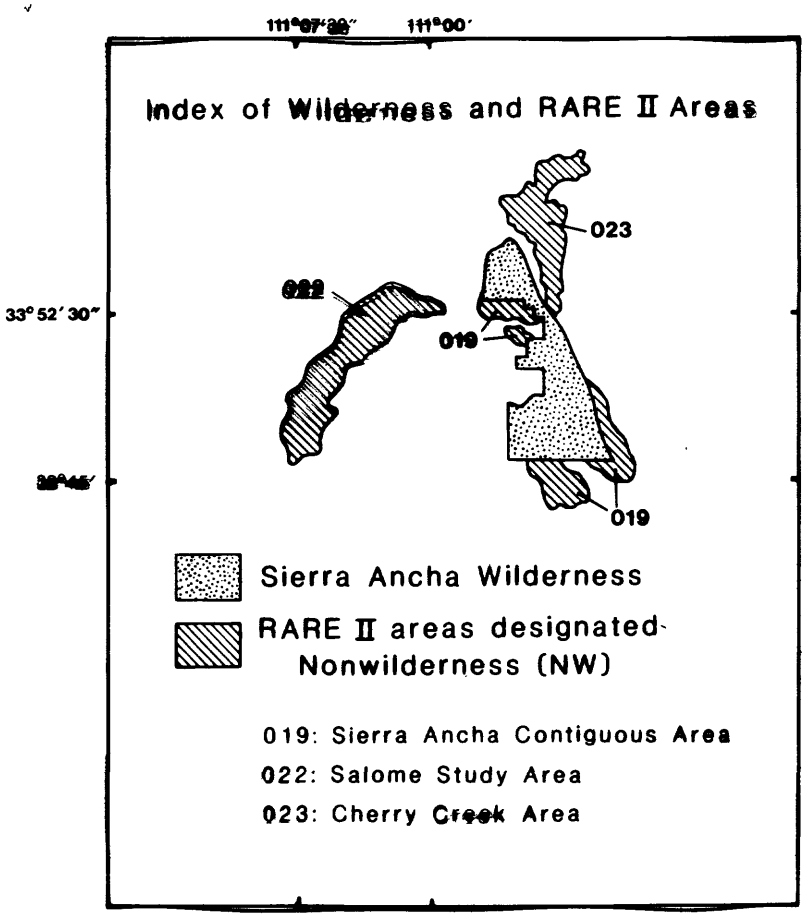

FIG. 2. Boundaries of Sierra Ancha Wilderness and Salome and Cherry Creek RARE II areas.

SAMPLE MEDIA SELECTION

Stream-transported sediments were chosen to provide as much compositing as possible. Two types were taken, the minus-30-mesh stream sediment and the nonmagnetic fraction of the heavy-mineral concentrate of the stream sediment. The minus-30-mesh stream sediment provides a geochemical cross section of the mechanically transported components of the drainage basin. Its composition is controlled mainly be the major geologic units. Minor components, such as an economic mineral deposit, can be seen in this media, but their influence is subject to significant dilution by the large amount of materials from the major units. A minus-30-mesh, rather than the more usual minus-80-mesh stream-sediment sample, was taken to reduce the influence of eolian dilution, and to speed sampling.

The nonmagnetic fraction of the heavy-mineral concentrate is used to obviate excessive dilution of ore-elements by ordinary rock minerals. Many of the ore minerals of an ore deposit are transported as detrital material that is mechanically resistant and of high specific gravity. They are concentrated in the field by panning, and later in the laboratory by heavy liquid and magnetic separation.

SAMPLE COLLECTION

Within an area of approximately 900 km^2, 215 sites were sampled (1 sample per 4 km^2). Stream channels draining basins 2 to 8 km^2 in area were sampled to provide two samples--a stream sediment and a heavy mineral concentrate. If water was not available for panning at the sampling site, two 1-liter cloth sample bags (5½ in. x 10½ in.) were filled with stream sediment passed through a 2-mm screen for panning at field camp. The panning was terminated when the heavy-minerals began to be lost, usually indicated by an abundance of magnetite, epidote, or hornblende (Theobald, 1957) or to approximately 200 grams.

Sample sites were plotted on the following topographic maps: Armer Mountain 7½', Copper Mountain 7½', Greenback Creek 7½', McFadden Peak 15', Rockingstraw Mountain 15', and Windy Hill 7½'. Location was recorded using Universal Transverse Mercator (UTM) metric grid coordinates.

Sample sites were assigned a SA prefix and a consecutive three digit number.

SAMPLE PREPARATION AND ANALYSIS

The dried minus-30-mesh stream-sediment samples were mechanically pulverized to approximately minus-150-mesh to provide a 10 mg sample for analyses for 31 elements by a six-step semiquantitative emission spectrographic method (Grimes and Marranzino, 1968). The panned concentrates were sieved to minus-30-mesh. A density separation using bromoform (specific gravity 2.80 to 2.98), separated the heavy minerals from quartz, feldspar, clay, and other low density minerals. The heavy-mineral concentrates were then split into three fractions on the basis of magnetic susceptibility, using a Frantz Isodynamic Separator. The nonmagnetic fraction obtained at 0.6 ampere primarily contains low-iron magnesium silicates, barite, apatite, sphene, zircon, tourmaline, anatase, along with most sulfide minerals and secondary minerals of base metals. This fraction was split, one part for microscopic mineral identification, and the other hand ground to provide a 5 mg sample for emission spectrographic analysis identical to the used for stream sediments.

DATA STORAGE AND PROCESSING

The emission spectrographic analytical results for the minus-30-mesh stream sediment and the nonmagnetic fraction of the heavy-mineral concentrates, along with the UTM grid coordinates of the sample site are presented on the following pages. An entry of "N" indicates the element was not detected. An entry of "<" indicates the element was detected at a concentration lower than the lowest standard for comparison. An entry of ">" indicates the concentrate to be greater then the specific highest standard. The values are reported in parts per million (ppm) except for Fe, Ca, and Mg; which are reported in percent.

The detection limits of the analytical method for stream-sediment samples are given in Table 1. The detection limits for the nonmagnetic fraction of the heavy-mineral concentrates are twice those of stream sediments, since the sample size is one-half as large.

The analyses, along with the UTM grid coordinates, are presented in Table 2 for stream sediment samples and in Table 3 for heavy mineral concentrate samples.

The analyses, along with the UTM grid coordinates, were entered in the U.S. Geological Survey computerized Rock Analysis Storage System (RASS) (VanTrump and Miesch, 1977).

Table 1.--Detection limits in parts per million for stream sediments determination by emission spectrographic method

Element	Detection limit	Element	Detection limit	Element	Detection limit
Ag	0.5	Cr	10	Sc	5
As	200	Cu	5	Sn	10
