INTRODUCTION

The inversion of transient soundings for a coincident loop system on a layered halfspace is provided by program NLSTCO. The numerical technique uses a general adaptive nonlinear least-squares algorithm originally developed by Dennis and others (1979), and extended externally for constrained nonlinear regression by Anderson (1982a). The corresponding forward problem solution--also required in the inverse solution--is defined in Anderson (1982b). The numerical integrations used in NLSTCO are by adaptive digital linear filtering as described in Anderson (1975) and Anderson (1982c). Because digital convolution (filtering) methods are used, practical solutions for layered earth models are reasonably fast on most computers.

This report summarizes the general nonlinear least-squares (NLS) method used in Anderson (1982a), but as applied to observed transient soundings obtained using a coincident or single loop system placed on an assumed horizontally layered earth model. In addition, the quasi-static case is assumed (i.e., displacement currents are neglected). The system must use an "on-off" step current source of arbitrary current, where the transient decay voltage is measured during the off-time (i.e., after $t > 0$ sec.). An arbitrary maximum of 10-layers (homogeneous and isotropic) may be used; however, with most present time-domain electromagnetic (TDEM) measurement systems, only a few layers are generally resolvable for the given time range.

To avoid repeating the notation and other details of the forward problem solution in this report, the reader is referred to Anderson (1982b)--which has been updated from the original published version. Similarly, details on the NLS method may be found in Anderson (1982a). The present report will provide a brief description of the calculations, specific program parameters, and the VAX operating instructions. Appendix 1 offers some suggestions in converting the VAX program to other computer systems; Appendix 2 lists a simple input/output test example (taken from a known forward solution model); and Appendix 3 gives a partial source listing (the complete source is available on the distributed tape, as described in Appendix 3).

SUMMARY OF CALCULATIONS

The NLS method described in Anderson (1982a) requires a twice-continuously differentiable nonlinear objective function F describing the model equation as a function of the unknown layer parameters (i.e., the conductivities and thicknesses of an MM -layered earth, $MM > 0$). In this case, F is given by the transient $V(t)$ defined in Anderson (1982b, p.6), as

$$V(t) = \frac{2}{\pi} C \int_0^{\infty} \operatorname{Re}[E(\sqrt{b})/E_0] \cos(bt) db, \quad (1)$$

where discrete observed values $[V(t_i), t_i, i=1,2,\dots,N]$ are given. In some cases (e.g., data stacking), an associated standard deviation s_i may also be known, and should be used

for a weighted least-squares solution (see parameter IWT=1 in Anderson, 1982a, p.14).

Optionally, F may be given in terms of converted apparent resistivity (see \$INIT parameter IOPT=1 below) instead of $V(t)$. In this case, the user must convert the observed transient data $[V(t_i), t_i]$ to apparent resistivity data $[\rho_a(t_i), t_i]$ using the same transformation as given in Raiche and Spies (1981, p.54-55), where the units should be $V(\text{volts/amp})$, $t(\text{seconds})$, and $\rho_a(\text{ohm-meters})$.

When F is defined as in eq. (1) and IOPT=0 (default), then any convenient unit may be used for V (e.g., volts/amp, millivolts/amp, etc.), since the constant C in eq. (1) can be determined in the least-squares to account for a scale (or amplitude shift) factor times $V(t)$.

For either IOPT=0 or 1 cases, the independent time variable $t > 0$ must be given in seconds and in ascending order, and is assumed to be known without error.

The unknown (nonlinear) model parameters are denoted by the vector $B(J)$, and has the following assumed order:

$B(1), B(2), \dots, B(MM)$ are the MM -layer conductivities (in mhos/m.),

$B(MM+1), B(MM+2), \dots, B(2*MM-1)$ are the $MM-1$ layer thicknesses (in m.), and

$B(2*MM)$ is a transient scaling (or amplitude shift) parameter depending on the form of F chosen via \$INIT parameter IOPT.

Thus, the discrete objective function F may be expressed for either $IOPT=0$ as

$$\left. \begin{aligned} F &= B(2*MM) [V(t_i, B(J), J=1, 2, \dots, 2*MM-1)/B(1)], \\ \text{or for } IOPT=1 \text{ as} \\ F &= B(2*MM) [\rho_a(t_i, B(J), J=1, 2, \dots, 2*MM-1)], \end{aligned} \right\} (2)$$

where $i=1, 2, \dots, N$ and $N > 2*MM \geq 2$ ($1 \leq MM \leq 10$). Note that the $IOPT=0$ form of F has been normalized by the unknown $B(1)$, so that $B(2*MM)$ is a scaling constant free from $B(1)$; the exact form of $B(2*MM)$ can be determined from Anderson (1982b), if desired, and is related to the constant C in eq. (1) above.

In terms of the NLS notation (Anderson, 1982a, p.11-12), let $X(I,1)=t_i$ and $Y(I)$ be the observed F in eq. (2), then the observed data matrix is

$$(Y(I), X(I,1), I=1, 2, \dots, N).$$

Since $V(t)$ can range several decades in magnitude for $t_1 \leq t \leq t_N$, it is advised when $IOPT=0$ that a weighted least-squares option be used (see $IWT=1$ or 2 , Anderson, 1982a, p.14-15), which requires the augmented data matrix

$$(Y(I), X(I,1), X(I,2), I=1, 2, \dots, N),$$

where $X(I,2)=s_i$ is the standard deviation ($IWT=1$) of observation $Y(I)$, or $X(I,2)$ is the variance ($IWT=2$). Note that if s_i is unknown, one could use the statistical weight (Bevington, 1969, p.108) of $1/Y(I)$ by setting $X(I,2)=Y(I)$ and $IWT=2$; in this case, this would be preferred over using unity weights ($IWT=0$). However when $IOPT=1$, $IWT=0$ can

generally be used, since the range of $\rho_a(t)$ is usually much less than the range of $V(t)$ in most cases.

The analytical partial derivative subprogram (PCODE) was not included in program NLSTCO, therefore the estimated derivative option (IDER=1) must be used, which requires only the forward problem solution subprogram (FCODE). See Appendix 3 listing of FCODE for the coding details, which follows the method described in Anderson (1982b) for computing $V(t)$ and (or) $\rho_a(t)$.

Because realizable layered earth models are sought to fit the given data, a constrained minimization type (SP=3 or 4) is advised, along with reasonable lower and higher parameter bound arrays, $BL(J)$ and $BH(J)$ respectively, where $BL(J) \leq B(J) \leq BH(J)$, $J=1,2,\dots,2*MM$ (see Anderson, 1982a, p.17). This approach limits parameter space searching, and in some cases may avoid false starts (or catastrophic overflow conditions from poor estimates and data). In addition, individual parameters can be fixed in the least-squares using parameters IP and IB (Anderson, 1982a, p.13). In particular for the IOPT=1 case, one can usually fix $B(2*MM)=1$, provided the observed (converted) apparent resistivities are properly scaled. Similarly, for the IOPT=0 case, $B(2*MM)$ can be fixed if the constant C in eq.(1) is known a priori. [Actually, if the system calibration is known, then the constant C can be determined; therefore $B(2*MM)$ should be fixed to reduce the number of unknowns, and to reduce the possibility of finding an

equivalent but highly improbable solution.] In any case, the user should attempt to give a reasonable starting guess vector $B(J)$ corresponding to the given data matrix. It is advisable to begin with a few layers (e.g., $MM=1$ or 2) before trying models with more layers. For present TDEM equipment, generally only a few layers are all that can be resolved, due mainly to the small discrete time range $t_1 \leq t \leq t_N$ and noise level in observing $V(t)$.

In general, one should not expect both $IOPT=0$ and 1 to yield the same exact solutions for a given data set--due mainly to data noise, discrete time-range given, scaling, and the use of different weighting options. For exact data (as in Appendix 2), both $IOPT=0$ and 1 produce nearly identical solution vectors; for noisy observed data, this is rarely true, although the earth models resolved by both cases should give approximately "equivalent layers" for good fitting cases (i.e., if small parameter errors and RMS error).

PARAMETERS, FILES AND DATA REQUIRED

All \$PARMS parameters (excluding the $ISTOP=0$ option), program files (FOR005-FOR016), and data ordering requirements used by NLSTCO are identical to those described in detail for subprogram NLSOL (Anderson, 1982a, p.9-21), and therefore will not be repeated here. However, note that the ordering of the \$PARMS estimated parameter vector $B(J)$ used by NLSTCO must be given exactly as described above in eq. (2). The \$INIT model parameters required by NLSTCO must

be given after the object-time format statement on FOR005 (see Anderson, 1982a, p.10, item 5). Also see the EXAMPLE below and Appendix 2 for a typical data input.

\$INIT PARAMETER DEFINITIONS

\$INIT parameters (nondefault parameters must be given):

MM= Number of layers in the model ($1 \leq MM \leq 10$; default MM=1 for a homogeneous half-space). Since NLSOL also requires the total number of parameters K, then make sure that $K=2*MM$ is given in \$PARMS also. (See the section ERROR MESSAGES below for a discussion on $K=2*MM$ dual input requirement.)

IOPT=0 (default) means that the data matrix $(Y(I), X(I,1), I=1, N)$ is given with $Y(I)=V(t)$ transient data, which may be unscaled and in any units as determined by $B(2*MM)$ in the least-squares solution. $X(I,1)=t_i$ must be given in seconds and in ascending order for $I=1, 2, \dots, N$.

IOPT=1 means the data matrix $(Y(I), X(I,1), I=1, N)$ is given with $Y(I)=\rho_a(t)$ apparent resistivity data (in ohm-m.). The shift parameter $B(2*MM)=1$ can be fixed via \$PARMS IP,IB provided the apparent resistivity is known to be scaled correctly. $X(I,1)=t_i$ must be given in seconds and in ascending order for $I=1, 2, \dots, N$.

A= Radius (in m.) of the transmitter circular loop, where $A > 0$ must be given. [Note that a square loop

of side L (m.) is considered equivalent to a circular loop of radius A (m.), where $A=L/\sqrt{\pi}$.]

EPS= Requested convolution integration tolerance used to compute all Fourier and Hankel transforms by digital filtering (default EPS=0.1E-9).

B0=1.E-3 (default) is the lower induction number for which the normalized E/E_0 frequency response (Anderson, 1982b) approaches the limit 1.0 for $B < B_0$. This assumption saves time by avoiding explicit response calculations for $B < B_0$. B_0 must be given (or assumed 1.E-3 by default) as a power of 10^{**n} (n integer). The default value is usually adequate for most models; for more accuracy in the late-time transient, $B_0 < 1.E-3$ can be used.

BM=1.E5 (default) is the upper induction number for which the normalized E/E_0 frequency response approaches the limit 0.0 for $B > B_M$. This assumption saves time by avoiding explicit response calculations for $B > B_M$. B_M must be given (or assumed 1.E5 by default) as a power of 10^{**n} (n integer). The default value is usually quite adequate for most models; for more accuracy in the early-time transient, $B_M > 1.E5$ can be used.

NB=6 (default) represents the number of induction number points per decade (log-cycle) to evaluate the pre-splined frequency response function $E(B)/E_0$. In general, $3 \leq NB \leq 11$ is usually adequate for most applications ($NB < 3$ is not recommended for accuracy

reasons). If NB=0 (or NB>11) is specified, then a direct mode of evaluating the frequency function is used but as controlled by the outer time-integral via lagged convolution (i.e., the cosine filter using subroutine RLAGF0). Note that NB=0 (or NB>11) is more accurate, but much more time-consuming than using NB<12. [See the section COMPUTER TIMING CONSIDERATIONS for a further discussion on the use of NB.]

\$END [end of \$INIT parameters; the "END" in \$END may be omitted, if desired.]

(See Appendix 2 for a complete input/output example.)

COMPUTER TIMING CONSIDERATIONS

The computer CPU-time will vary mostly as a function of the given \$INIT parameters MM, EPS, B0, BM, NB and \$PARMS parameters N, NITER, IP, SP, IV, V, and B. Perhaps the parameters of greatest effect on CPU-time are how good the initial model estimates are given in array B(J), J=1,2,...,2*MM, with respect to the observed data matrix. Of course, the observed data matrix time-range and noise level can contribute further problems in resolving a given layered earth model for any MM in (1,10). In some cases, it may be necessary to fix certain parameters in B (via \$PARMS IP, IB) that cannot be resolved and/or to control the initial theoretical transient curve behavior. Generally, it is best to begin with a small MM (say 2 or 3), and progressively increase MM until the RMS error cannot be further decreased. During this "initial model searching study", several \$INIT parameters can be modified (relaxed) to significantly reduce the overall CPU-time, but with somewhat less accurate results (which may not be needed for initial runs). Some suggestions are provided in Table 1.

Table 1. Recommended \$INIT parameters for NLSTCO

\$INIT parameter	Default value	Faster CPU; less accurate	Slower CPU; more accurate
EPS	0.1E-9	0.1E-5	0.1E-11
B0	1.E-3	1.E-2	1.E-4
BM	1.E5	1.E4	1.E6
NB	6	2<NB<6	6<NB<12

For a final model run, the default values in Table 1 are generally sufficient for most field situations, with the exception that $NB > 6$ may be used to reduce any noticeable nonsmoothness in the calculated transient. (Note that $NB > 11$ is not recommended for routine field work.)

Some \$PARMS parameters used in the NLS algorithm can also be modified to reduce the total CPU-time when searching for an initial model. In particular, \$PARMS NITER (Anderson, 1982a, p. 16) can be set small (e.g., 3 or 5) to force termination of a trial run after just a few iterations. This is reasonable, since it may not be necessary to obtain normal convergence of the iteration process for preliminary or intermediate models. Other \$PARMS that control the NLS algorithm speed and accuracy can also be overridden from their default values (see Table 2 in Anderson, 1982a, p. 20-21 for more details).

DATA MATRIX NOTES

The data matrix (defined following eq. (2)) is read under the object-time format statement, and is defined as the sequence of ordered rows:

$$(Y(I), (X(I, L), L=1, M^*), I=1, N),$$

where $M^* = M$ if $IWT=0$ (default), or $M^* = M+1$ if $IWT=1$ or 2 . In the above example, $IWT=1$, $M=1$, and therefore three columns are required in the data matrix row, where in this case, the last column represents the standard deviation of observation

Y(I).

SPECIAL OBJECT FORMAT PHRASES

If an existing data matrix file does not have the proper defined column ordering in the form (Y(I),X(I,J),J=1,M), then the FORTRAN "Tn" format phrase may be used to begin at any column n in the data record. For example, the format (T41,F10.0,T1,2F10.0) will select Y(I) using column 41-50 and X(I,1) beginning at column 1. See any FORTRAN-77 coding manual for other allowable object (run) time format phrases (e.g., the G-format, use of "/" to skip records, etc.). Note that "tab"-characters must not be used when creating the data matrix file FOR010.

VAX OPERATING INSTRUCTIONS

In general, the basic steps described to run NLSOL (Anderson, 1982a, p.22-24) can be followed to run NLSTCO either on-line or in batch mode. That is, the parameter and data matrix files may be associated with the logical names FOR005 and FOR010, respectively, using the VAX-DCL statements:

```
$ASSIGN parameterfilename FOR005
```

```
$ASSIGN datamatrixfilename FOR010
```

```
$RUN NLSTCO !(use $RUN [WANDERSON]NLSTCO on USGS VAX)
```

If the data matrix is included on FOR005 (i.e., using IALT=5), then the FOR010 assignment is not necessary.

In addition, program NLSTCO has a useful "restart file" (called FOR005.TMP) that is automatically provided each time the program is executed. File FOR005.TMP contains a copy of all parameters on FOR005, plus the last solution B-vector obtained; note that \$PARMS ISTOP=0 (Anderson, 1982a, p.14) cannot be used because FOR005 is positioned at EOF in creating FOR005.TMP. If desired, one can easily continue (or restart) more iterations simply by using the DCL commands:

```
$ASSIGN FOR005.TMP FOR005
```

```
$RUN NLSTCO !(use $RUN [WANDERSON]NLSTCO on USGS VAX)
```

Note that FOR005.TMP may also be edited (using any VAX editor) for other parameter changes, if desired. Also, the reassignment of FOR005 using FOR005.TMP only needs to be done once for multiple continuation runs.

By default, the master print (disk) file is called FOR016.DAT, unless otherwise assigned. This file can be TYPed or PRINTEd on a line printer. Also, file FOR016 may be used as an input file to a plot routine; e.g., to plot the observed (OBS), calculated (CAL), and residual (RES) curves. If program NLSTCO is run on-line, then a shorter terminal print file on FOR006 contains some of the information as on FOR016, but as controlled by parameter IPRT (Anderson, 1982a, p.15).

ERROR MESSAGES

Almost all \$PARMS syntactical errors are flagged and printed on files FOR006 and FOR016 and the job is aborted (see Anderson, 1982a, p.24). However, some cross-references (or dual inputs) are not checked; for example, the relationship $K=2*MM$ is not double checked between \$PARMS K and \$INIT MM parameters. This is because a general-purpose nonlinear least-squares algorithm (NLSOL) is being used as a control program, but the model input is external to the particular nonlinear problem requirements (NLSTCO) read by subprogram SUBZ (see Anderson, 1982a, p.38). Therefore, the user is responsible for providing exactly K parameter estimates in $B(I), I=1,2,\dots,K$ (see eq. (2)), and that \$INIT MM is such that $K=2*MM$ (otherwise, unpredictable results could occur).

The message "{WARN}: NOISE IN CALC. TRANS DETECTED" can occur for certain model estimates in array B with respect to the given data matrix. This warning message actually means that the calculated transient voltage V/I cannot be computed accurately at late times using single-precision arithmetic (regardless of the values specified in \$INIT parameters EPS, B0, BM, and NB). However, this condition is usually unimportant if the warning occurs near the beginning of the NLS iteration. For typical field data cases, and a moderate MM value and reasonable B estimates, one should not expect the warning message to appear near the end of the NLS iterations for a converging model solution.

PRINTED OUTPUT

All input parameters are output on files FOR006 and FOR016, with the \$INIT parameters given first, followed by all \$PARMS parameters given or assumed by default. (Refer to Appendix 2 for a complete sample output listing.)

Specific names (e.g., IT, NF, ...) used by NLSOL in the output listings are tabulated in Anderson (1982a, p.25-26). Program NLSTCO provides a summary listing of the final solution vector B, along with accumulated layer thicknesses listed under the DEPTH column (see the end of the listing example in Appendix 2). The RESISTIVITY column is simply $1/\text{SIGMA}$, where SIGMA is the layer conductivity (in mhos/m.).

Appendix 1.-- Conversion to other systems

This program (and associated subprograms) was written in ANSI-standard FORTRAN-77 for the VAX-11/780 system (VMS version 2.5). Conversion to systems without an ANSI-FORTRAN-77 compiler would necessitate extensive changes, particularly for all CHARACTER-type variables, IF-THEN-ELSE phrases, etc.

Since the FORTRAN-77 ANSI-standard presently does not provide for a NAMELIST I/O capability, a VAX-11 NAMELIST simulator subprogram is included in this program package. For most large main-frame systems (e.g., IBM/370, CYBER, etc.), a NAMELIST READ/WRITE is usually available; in this case, the VAX NAMELIST subprogram and associated routines (DECODEIX, DECODEX) can be eliminated; also, appropriate changes can be made where COMMON/NAME_LIST/ and CALL NAMELIST is used in the source program.

Other changes for non-VAX systems might include some (or all) of the following:

- (1) Variables with more than 6-characters.
- (2) Use of the underscore character or dollar character in some variables and/or COMMON names.
- (3) Character strings delimited by single-quote characters (e.g., 'STRING'); also, character string concatenation (e.g., 'STRING1'//'STRING2').
- (4) Passing variable-length character strings in subroutine calls; e.g., CHARACTER*(*) passed length character

arguments.

- (5) Need to suppress arithmetic or exponential underflow messages (note that a VAX-11 result is automatically set to 0.0 after any underflow--which is assumed for this program package); if the target system does not set underflows to 0.0 (and suppress warning messages), then a suitable conversion procedure must be used for proper operation of this program package.
- (6) Replacement of any special VAX-dependent CALLS or statements (e.g., CALL LIB\$INDEX, ACCEPT, TYPE, CALL SYS\$anyname, etc.--note that we have minimized machine-dependent calls, where possible).
- (7) Hexidecimal constants (e.g., '4A'X) if used in any DATA statements.
- (8) Virtual-sized arrays, if any (i.e., DIMENSION statements greater than physical memory).

Appendix 2.-- Test problem input/output listing

The following input files (FOR005.0, FOR010, FOR005.1) were used to run a known test problem for program NLSTCO on a VAX system using both IOPT=0 and 1 cases separately. The corresponding output files (FOR016) are given following FOR005.1. In addition, each file FOR016.DAT was used to plot the final observed (OBS) and calculated (CAL) curves using an external plotter. The symbol "O" represents Y(I) in the plot, and the solid line represents a curve drawn through the calculated (CAL) points.

Appendix 3.-- Source code availability and listing

Source Code Availability

The current version of the source code may be obtained by writing directly to the author*. A magnetic tape copy can be sent to requestors to be copied and returned. This method of releasing the source code was selected in order to satisfy requests for the latest (e.g., possibly updated) version. [The attached listing does not include the adaptive nonlinear least-squares algorithm (Dennis and others, 1979) due to its length; however, the complete algorithm is available on the distributed tape.]

The magnetic tape is usually recorded in the following mode (unless requested otherwise):

Industry compatible: 9-track, standard ANSI-labeled, ASCII-mode, odd-parity, 800-bpi density, 80-character card-image records (blocked 50-card images, or 4000-characters, per physical block), and contained on a file named "NLSTCO.VAX".

* present address is:

U.S. Geological Survey
Mail Stop 964
Box 25046, Denver Federal Center
Denver, CO 80225

Source Listing

      SUBROUTINE NLSOL(FCODE,PCODE,SUBZ,SUBEND)
C
C {NLSOL}: GENERAL NONLINEAR LEAST-SQUARES SOLUTION {2/8/82}
C USING DENNIS ET AL (1979; SEE REF1 BELOW)
C ADAPTIVE NONLINEAR LEAST-SQUARES ALGORITHM.
C
C** THIS IS AN INTERFACE ROUTINE WRITTEN FOR THE VAX-11/780 BY
C W.L.ANDERSON, U.S.GEOLOGICAL SURVEY, DENVER, COLORADO.
C
C** THIS INTERFACE (NLSOL) HAS ADDITIONAL OPTIONS (BESIDE REF1) TO:
C (1) PERFORM EITHER UNCONSTRAINED OR UP TO 4-TYPES OF CONSTRAINED
C ADAPTIVE NONLINEAR REGRESSION FOR ARBITRARY NONLINEAR PROBLEMS.
C (I.E., PARTIAL OR FULL LOWER/HIGHER PARAMETER BOUNDS, ETC.)
C (2) HOLDING CERTAIN PARAMETERS FIXED (I.E., AS CONSTANTS) IN THE
C LEAST-SQUARES (THIS IS ANOTHER FORM OF CONSTRAINING SOLUTION
C SPACE).
C (3) PROVIDE FOR WEIGHTED OBSERVATIONS (I.E., WEIGHTED LEAST-SQUARES)
C (4) OBJECT (RUN)-TIME CONTROL OF READING THE DATA MATRIX, PLUS
C MANY OTHER I/O OPTIONS, ETC.
C (5) OPTIONALLY, ONE CAN USE EITHER ESTIMATED PARTIAL DERIVATIVES, OR
C ANALYTICAL PARTIAL DERIVATIVES (IF SUBROUTINE PCODE AVAILABLE).
C
C** THE USER ONLY NEEDS TO WRITE SUBROUTINES FCODE, PCODE, SUBZ, AND
C SUBEND (SEE DETAILS BELOW) EXACTLY AS USED IN SUBROUTINE 'MARQRT'
C (SEE REF2) OR 'IMSLMQ' (SEE REF3). ALSO, THE SAME PARAMETER FILE
C FOR005 AND OBJECT (RUN)-TIME DATA MATRIX FILE FOR010 AS USED BY
C EITHER MARQRT OR IMSLMQ MAY BE USED IN 'NLSOL'.
C
C** NLSOL CALLS NLITR WHICH CALLS 'NL2ITR' AS PUBLISHED BY DENNIS ET AL,
C (SEE REF1, P. 38), OR 'NL2SNO' (SEE REF1, P. 35).
C
C** REF1: DENNIS, J.E., ET AL, 1979, AN ADAPTIVE NONLINEAR LEAST-
C SQUARES ALGORITHM, NTIS REPORT AD-A079-716.
