tons (short)	0.907	metric tons (t)
miles	1.609	kilometers

## CONVERSION FACTORS

For use of readers who prefer to use metric units, conversion factors for terms used in this report are listed below:

<u>Multiply</u>	<u>By</u>	<u>To Obtain</u>
foot (ft)	0.3048	meter (m)
inch (in.)	25.40	millimeter (mm)
British thermal unit per pound (Btu/lb)	2.326	kilojoules per kilogram (kJ/kg)
tons (short)	0.907	metric tons (t)
miles	1.609	kilometers

This map and companion text were prepared from published, or otherwise publically available information, no proprietary data were used in these compilations. Geologic information, that pertains to the occurrence of resources on Indian lands or local fee lands was used in its compilation, wherever these data were readily available.

## Introduction

This map report is one of a series of geologic and hydrologic maps for States in the Basin and Range province. The map reports contain detailed information on subjects including ground-water hydrology, ground-water quality, surface distribution of selected rock types, tectonic conditions, areal geophysical data, Pleistocene hydrologic features, and mineral resources that characterize the Basin and Range province. This work is a part of the U.S. Geological Survey's program for geologic and hydrologic evaluation of broad physiographic provinces to identify potentially suitable environments for storage of high-level nuclear waste (Bedinger, Sargent, and Reed, 1983).

This map and companion text were prepared from published, or otherwise publically available information, no proprietary data were used in these compilations. Geologic information, that pertains to the occurrence of resources on Indian lands or local fee lands, was used in its compilation, wherever these data were readily available.

Arizona	June 1, 1982
California	April 18, 1981
Idaho	January, 1982
Nevada	September 23, 1982
New Mexico	March 10, 1983
Oregon	April 1, 1982
Texas	July 1, 1981
Utah	January, 1982

Oil and gas seeps and tar sandstone occurrences were also plotted as an indication of petroleum or hydrocarbon integrated rock deposits.

Coal data shown on the map include the location of prospects, mines and principal fields. No attempt was made to determine the extent of coal-bearing strata in the subsurface by using data from coal test holes. Occurrences of coal or potentially coal-bearing rock were plotted outside of the Basin and Range boundary when these areas occur within hydrologic units that are included as part of the project study area. The coal data summaries provide a very general description of the geologic character for each mapped occurrence of coal. No attempt was made to outline the production history for individual areas, or to tabulate coal quality data.

Oil and gas wells were mapped as producing wells or dry holes. Holes with shows of oil or gas were not mapped separately, because the task of verifying this information is beyond the present scope of the project. Published sources, which describe similar data, are commonly contradictory and frequently not verified. The most recent posting date for wells in each State is as follows:

Arizona	June 1, 1982
California	April 18, 1981
Idaho	January, 1982
Nevada	September 22, 1982
New Mexico	March 10, 1983
Oregon	April 1, 1982
Texas	July 1, 1981
Utah	January, 1982

Oil and gas seeps and tar sandstone occurrences were also plotted as an indication of petroleum or hydrocarbon impregnated rock deposits.

The classification of leasable mineral lands within the public domain was not depicted, because these areas are continually redefined.

Location: Cochise County, at the northern end of the Chiricahua Mountains near Cochise Head.

Summary of selected data for coal fields

Arizona: Creek Field

Chiricahua Mountains County (eastern).

Location: Cochise County, at the northern end of the Chiricahua Mountains near Cochise Head.

Rank: Bituminous. Coal makes a low-grade coke; ash

Age: Originally described to be Carboniferous (Dumble, 1902, p. 230); now believed to be Cretaceous (Hayes in Averitt and O'Sullivan, 1969, p. 67).

Comments: Two principal beds 24 in. to 30 in. thick.

Rank: No analyses available; coal described as glossy-black graphitic anthracite. thin beds.

Comments: High ash content, difficult to ignite.

Selected Thickness locally exceeds 12 ft.

Arizona:

Deer Creek Field

Location: Pinal County (eastern).

Age: Late Cretaceous.

Rank: Bituminous. Coal makes a low-grade coke: ash content is high (18.7-54.4 percent), Campbell (1904, p. 254-256).

Comments: Two principal beds 24 in. to 30 in. thick. Beds of clean coal average 12 in. to 15 in. maximum thickness. Several thin beds. Coal is not laterally extensive.

Willden, Ronald, 1964, Geology of the Christmas Quadrangle, Gila and Pinal Counties, Arizona: U.S. Geological Survey Bulletin 1161-E, 64 p.

Arizona:

Mogollon Rim

Location: Gila County (northwest part), between Fossil Creek Canyon (to northwest) and Canyon Creek (to southwest).

Age: Permian (lower Wolfcampian), 3 "coaly" units occur within a 30 ft section of light gray shales about 600 ft to 800 ft below Fort Apache Member of Supai Formation (McGoon, 1962, p. 89).

Rank: Estimated to be lignite (Ransome, 1916). Bituminous (10,000 Btu/lb.) for oxidized material (McGoon, 1962, p. 89). Likely to be highly variable throughout extent of occurrence.

Comments: Maximum coal bed thickness 15 in. Associated with minor amounts of copper and uranium.

Arizona:

Pinedale Field

Location: Navajo County, extends into northern part  
of the Fort Apache Indian Reservation.

Age: Cretaceous, Mesaverde Group, Mancos Shale  
equivalent (Miller, 1966, p. 93).

Rank: Variable. Impure, subbituminous to high-  
volatile bituminous coal. High sulfur,  
volatile content. Cooper (1947, p. 32).

Comments: Coals are generally 3 ft to 4 ft thick,  
and locally very dirty coal may attain 6  
ft thickness within a 12 ft thick section  
of bony coal and carbonaceous materials.

Whetstone Mountains

Location: Pima County, southwestern part of Whetstone Mountains (Schrader, 1915).

Age: Early Cretaceous

Rank: Lignite. No analyses available.

Comments: Coal occurs within a 40 ft section of sandstone, shale, and siliceous claystone. Exploratory workings were developed for 1,000 ft along outcrop of 4 in. thick beds. Animal and plant remains, as well as large petrified trees, occur near the coal-bearing rocks.

California:

Colorado Camp Group (Gerbracht Camp, French Deposit, Randsburg Coal).

Location: Kern County, El Paso Mountains, SE1/4 sec. 36, T. 28 S., R. 38 E.

Age: Paleocene and Eocene (lower part of Goler Formation)

Rank: Sandy lignite. No analyses available.

Comments: Four beds of coal 22 in., 26 in., 14 in., and 18 in., were mined from 3 shafts at depths of 60 ft, 100 ft, and 145 ft. Production was limited to 220 tons in 1898.

Idaho:

Goose Creek Field

Location: Cassia County Idaho.

Age: Miocene and Pliocene(?), Payette Formation;  
Miocene and Pliocene, Salt Lake Formation.

Rank: Lignite.

Comments: Lignite has been mined in small quantities for local use from both formations. High ash content. Some uranium mineralization occurs locally in lignite (Idaho, T. 16 S., R. 21 E.) along the flanks and trough of a shallow syncline.

Selected References:

Willow Creek-Caribou District

Location: Bingham, Bonneville Counties.

Age: Early Cretaceous; Bear River and Wayan Formation.

Rank: Lignite.

Comments: Carbonaceous shale and lenticular units of lignite occur as thin beds, that range in thickness from a few inches to more than 7 ft. Coals are very high in ash and moisture content. Exploration in the area occurred during the early 1900's. The Cloward, Brimson [Miller mine of Schultz (1918)], and Croley mines were adits that were driven for short distances to explore carbonaceous and lignitic shales. Thickest coal encountered in any of these prospects was about 1 ft. No production has been recorded from any of these mines.

Nevada:

Bald Mountain

Location: Humboldt County, southern end of the Humboldt Range.

Age: Mississippian; Diamond Peak Formation.

Rank: Subbituminous; high ash and volatile content.

Comments: Coal bed thickness is generally between 2 to 7 in. Workings are limited to a single adit about 160 ft deep. Mississippian outcrops in the vicinity of Bald Mountain are limited in areal extent to a few square miles. No resource or production information is currently available for coal at Bald Mountain.

Nevada:

Carlin

Location: Elko County, south side of the Humboldt River, 2.5 miles east of Carlin. T. 33 N., R. 53 E., section 13.

Age: Tertiary.

Rank: Not available.

Comments: The Humboldt Coal Company was formed in 1870 to develop this property. A short adit was driven 15 ft below the surface into the river bank. No production is reported from the area.

Nevada:

Cherry Creek

Location: White Pine County, southern end of the  
Cherry Creek Range, NE1/4 section 24,  
T. 25 N., R. 62 E.

Age: Mississippian.

Rank: High-volatile C bituminous.

Comments: Limited workings in single adit. No  
resource or production information is  
presently available.

Nevada:

Coaldale Field

Coal Creek

Location: Esmeralda County.

Location: Washoe County, Pah Rah Range.

Age: Tertiary.

Age: Tertiary.

Rank: Bituminous. High percentage of ash, sulfur,

Rank: Lignite. Lignite matter.

Comments: A single coal bed, which is 4 ft thick, is reported to occur 30 ft below the surface. This coal is associated with carbonaceous shale, and the coal-bearing strata is overlain by ash-flow tuffs.

Nevada:

Coaldale Field

Location: Esmeralda County.

Age: Tertiary.

Rank: Bituminous. High percentage of ash, sulfur, and volatile matter.

Comments: Thin coals are associated with volcanic ash, bentonite and shale. Coal beds are usually between 3 ft and 7 ft thick, and occur at 4 horizons in moderately inclined, extensively fractured and faulted rocks. Production was very limited.

Nevada:

Eldorado Canyon Mine

Location: Carson City area. Southeast of Dayton,  
section 6, T. 14 N., R. 22 E.

Age: Tertiary, Miocene.

Rank: Lignite.

Comments: Coal beds are associated with claystones,  
tuffs, and andesites. The property has been  
developed by 2 shafts. No production data  
have been published to date.

Nevada:

Elko

Location: Elko County, NW1/4 NE1/4 section 27,  
T. 34 N., R. 55 E.

Age: Tertiary.

Rank: Lignite.

Comments: A thin coal bed, which is 0.5 ft thick,  
is associated with an oil shale sequence  
in the Eocene and Oligocene(?) Elko Formation.  
Coal-bearing strata are overlain by a  
thick tuff unit.

Nevada:

Gamma Prospects (Gamma No. 1, Gamma No. 2)

Location: Churchill County, west side of the  
Desatoya Mountains, T. 16 N., R. 37 E.

Age: Tertiary.

Rank: Lignite; very high ash content, which  
ranges from 59 to 75 percent.

Comments: Coal-bearing strata generally strike  
east and dip north from 2 to 21 degrees.  
Folding and faulting are not common in  
the area. The coals are associated with  
claystones and sandstones, and extend  
laterally along the outcrop for 1285 ft.  
There are five thin beds exposed near  
the base of the sedimentary section.  
Thicknesses for these lignite beds from  
top to bottom are: 0.3 ft, 0.1 ft,  
0.6 ft, 0.1 ft, and 3.5 ft. The  
thickest coal bed is associated  
with varying amounts of uranium.

Nevada:

Goose Creek Field

Location: Elko County, Nevada.

Age: Miocene and Pliocene(?); Payette Formation;  
Miocene and Pliocene; Salt Lake Formation.

Rank: Lignite.

Comments: Lignite has been mined in small quantities for local use from both formations. High ash content. Some uranium mineralization occurs locally in lignite (Idaho, T. 16 S., R. 21 E.) along the flanks and trough of a shallow syncline.

Nevada:

Lewis Coal Mine

Location: Lyon County; Coal Valley south of Yerrington, and 18 miles north of Aurora. Section 36, T. 8 N., R. 27 E., and section 1, T. 7 N., R. 27 E.

Age: Tertiary.

Rank: Subbituminous. Ash content averages 16 percent, moisture 14 percent, and volatile hydrocarbons 30 percent.

Comments: Coal beds vary from 3 ft to 8 ft thick. The Nevada Coal and Oil Company developed the property with 2 adits 700 ft and 900 ft long, and an inclined shaft 400 ft deep. No coal production data are available at present.

Pahranagat

Location: Lincoln County; 15 miles from Hiko.

Rank: No data available. Originally described as

Age: anthracite. Ash residue less than 3 percent after burning in a muffle furnace.

Rank: Not available; possibly lignite.  
Comments: Surface exposure of 15 ft thick bed mentioned in original description. No additional information is currently available.

Palisade Coal Mine

Location: Eureka County; T. 32 N., R. 51 E,  
section 25.

Age: Tertiary.

Rank: No analyses available; probably bituminous.

Rank: Not available; possibly lignite.

Comments: The area was explored by a 30 ft shaft  
and a drift 175 ft long. No information  
pertaining to the extent, quality, or  
production of coal is available.

Nevada:

Pancake Coal Mine

Location: Western White Pine County.

Age: Mississippian.

Rank: No analyses available; probably bituminous.

Comments: Thin coals, generally 10 to 18 inches thick crop out for 150 ft along strike. The maximum thickness of coal is reported to be 5 ft. Coal and the enclosing strata are fractured and displaced by faulting. Some mining has occurred; however, no production information is available at present.

Nevada:

Table Mountain

Location: Not known.

Age: Tertiary.

Rank: Lignite.

Comments: Coal has been reported from the vicinity of Table Mountain. No surface exposures or evidence of any workings are apparent; however, coal may be present in small amounts in the local Tertiary sediments.

Nevada:

Verdi

Location: Washoe County, T. 19 N., R. 18 E.,  
section 9.

Age: Tertiary.

Rank: Lignite. High in ash content and volatile  
matter.

Comments: The property was explored by the Nevada  
Carbon Company in the early 1940's. No  
data are available for coal resources or  
production.

General References Selected for Coal

Wilson District (Pine Grove District)

Location: Lyon County, 2 miles from Pine Grove.

Age: Late Miocene to Middle Pliocene; Coal Valley Formation.

Rank: Lignite.

Comments: Coal with numerous claystone partings is associated with shale near Pine Grove.

The thin beds, which are between 6 in. and 2 ft thick, crop out for 100 ft, and there is no evidence of any workings.

Mexico:

### Carthage Field

Location: East-central Socorro County.

Age: Late Cretaceous; Mesaverde Formation.

Rank: High-volatile C bituminous. This coal makes an excellent coke, and was used by New Mexico smelters during the late 1800's and early 1900's.

Comments: Two coal beds occur in the lower 100 ft of the Mesaverde Formation. The Carthage coal bed, which occurs 40 to 60 ft above the base of the Mesaverde, attains a maximum thickness of 6 ft, and was mined from 1861 through the mid 1950's.

The coal-bearing strata occurs along an extensively faulted nose of a south plunging anticline. Fault-bounded blocks are uplifted, and internally fractured.

Structure controls, mining which is limited to single-fault blocks.

Most easily mined coal has been removed. Additional resources possible, east and south of mined-out areas.

## New Mexico:

### Cerrillos Field

Location: South-central Santa Fe County.

Age: Late Cretaceous; Mesaverde Formation.

Rank: Variable; primarily bituminous. Range is from bituminous to anthracite. Most bituminous coal is non-agglomerating; however, some coking coal has been mined.

Comments: The three principal beds that have been mined in the area are, from oldest to youngest: Miller Gulch, Cook and White, and White Ash coal beds. The last two beds were the principal mining targets near Madrid.

The area is structurally complex. Faults, sills and dike swarms are common. The White Ash coal bed has been metamorphosed to anthracite near intrusives. Coal, which was produced from more than 30 mines during the period 1888-1957, was shipped throughout the central and western U.S.

New Mexico:

Datil Mountain Field

Location: Valencia, Socorro, and Catron Counties.

Age: Late Cretaceous. Gallup Sandstone, and Crevasse Canyon Formation. Lower part of Mesaverde Group.

Rank: Primarily subbituminous; locally bituminous.

Comments: Coal and carbonaceous shale occur at several stratigraphic horizons. Most coal is very thin, and single coal beds rarely exceed 3 ft in thickness. Locally coal may be 5 ft thick. The area is characterized by a synclinal structure, which has been subjected to folding, faulting, and igneous intrusion. A thick sequence of volcanic rocks covers the coal-bearing rocks toward the south.

Access to the area is very difficult, and little coal has been mined.

New Mexico:

Engle Field

Location: Central Sierra County.

Age: Cretaceous; lower part of the Mesaverde Group.

Rank: Subbituminous.

Comments: Thin coal beds, that are associated with carbonaceous shales crop out along the western edge of the Jornada del Muerto syncline. Coal-bearing strata dip steeply eastward along the eastern side of the Fra Cristobal and Caballo Mountains. Dips flatten eastward toward the central part of the valley. Coal is generally less than 5 ft thick.

The first shaft in the area was sunk in 1905; 3 mines operated briefly during the height of development. The coal was used by miners near Palomas Gap to reduce metallic ores.

Hagen Field (Una del Gato)

Location: South-central Sandoval County.

Age: Late Cretaceous; Mesaverde Formation.

Rank: High-volatile C bituminous.

Comments: Development is limited because of very common faulting and abundant intrusions along the coal-bearing homoclinal structure. The maximum coal bed thickness is 5 ft, however, most beds are less than 4 ft thick.

Four small underground mines operated between 1900 and 1939. Production ceased because of transportation problems and difficult mining conditions.

# Jornada del Muerto Field

Location: Eastern Socorro County.

Age: Late Cretaceous; Mesaverde Formation.

Rank: High-volatile C bituminous. Coal from the Law mine makes a poor to fair coke.

Comments: Coal-bearing strata occur along the western limb of the Prairie Springs anticline. Coal beds are lenticular, and are commonly less than 3 ft thick. The southern part of the field is covered by gravel and wind-blown sand. There is no recorded production.

New Mexico:

Pecos River (Gould and Thomas, El Porvenir, Cowles Mines). The majority of these occurrences are immediately adjacent to the Basin and Range study area.

Location: Santa Fe, San Miguel Counties.

Age: Pennsylvanian.

Rank: Bituminous (?).

Comments: Isolated occurrences of bituminous coals, which are generally less than 40 in. thick, occur in the Lower and Middle Pennsylvanian La Pasada Formation east of Santa Fe. These coals were explored by three short drifts called the Gould and Thomas, (section 5, T. 16 N., R. 12 E.) El Porvenir, (sections 12 and 13, T. 17 N., R. 14 E.) and Cowles mines, (section 28, T. 18 N., R. 12 E.). Data for these coals is scarce and no resource information is currently available.

## Rio Puerco Field

Location: Bernalillo, Sandoval, and Valencia Counties.

Age: Cretaceous; Gibson Coal Member of the Crevasse Canyon Formation; Menefee Formation; and an undivided Gibson-Menefee unit.

Rank: High-volatile C bituminous.

Comments: The coal field lies west of the Rio Grande depression within the Rio Puerco fault zone. The few faults in the area are usually short, trend northeast, and dip between 45 degrees to 85 degrees westward.

Coal beds are lenticular, and the stratigraphic units, which contain the most coal, are the Menefee Formation and the middle to upper part of the Gibson Coal Member of the Crevasse Canyon Formation. Coals commonly vary from 1 to 3 ft in thickness; however, locally one bed attains a maximum thickness of 12 ft. Coal has been produced in small amounts from a few mines for local consumption.

Spiegel, Zana, and Baldwin, Brewster, 1963, Geology and water resources of the Santa Fe area, New Mexico: U.S. Geological Survey Water-Supply Paper 1525, p. 83-84.

Santa Fe location: Southwest Lincoln and northern Otero Counties.

Location: Northeast of Santa Fe, SE1/4, SW1/4, sec. 9, T. 17 N., R. 10 E. This area is just outside of the study area boundary.

Rank: Variable, principally bituminous.

Age: Pennsylvanian, upper clastic part of the Sandia Formation of the Magdalena Group.

Comments: Mined from several mines between 1885 and

Rank: Subbituminous. Coal is impure, contains much bone, and carbonaceous shale is also present.

Comments: Kottowski (in Spiegel and Baldwin, 1963, p. 83) estimated several hundred tons of coal and carbonaceous shale were mined from limited underground workings in the SE1/4 SW1/4 sec. 9, T. 17 N., R. 10 E. The lenticular coal attains a maximum thickness of 5 ft, and dips 44 degrees east. This coal occurrence occupies the same stratigraphic position as coal beds, which occur nearby along the banks of the Pecos River.

Sierra Blanca Field

Location: Southwest Lincoln and northern Otero Counties.

Age: Late Cretaceous; Mesaverde Formation.

Rank: Variable; principally bituminous.

Comments: Coal beds from 2 ft to 7 ft thick were mined from several mines between 1885 and 1939. Production declined substantially after 1910. Faulting and intrusions, which are common in the area, have limited development.

## Tijeras Field

Location: Northeastern Bernalillo County.

Age: Late Cretaceous; Mesaverde Formation.

Rank: Bituminous.

Comments: Coal-bearing strata occur in a syncline within the Tijeras graben. The coal beds are generally 1 to 2.5 ft in thickness. Three small mines produced small quantities of coal for local use during the early 1900's.

Oregon:

Lignitic units, generally less than 1 meter thick, presumably occur in the Miocene and Pliocene(?) Payette Formation equivalents in the area of the Alvord Desert, where they yield natural gas shows when penetrated by drill holes (Fouch, T. D., 1983, personal communication). There is currently no commercial production of coal in the Basin and Range province in Oregon.

Texas:

Eagle Spring

Location: Hudspeth County, Eagle Mountains.

Age: Late Cretaceous, Chispa Summit Formation of Adkins (1933).

Rank: Probably bituminous. Information scarce, contradictory. High ash and volatile content. Some coal metamorphosed to anthracite.

Comments: Four principal coal beds which range from 20 in. to 7 ft in thickness. Average thickness, 3.5 ft.

Coal was most likely deposited in stagnant lagoons. The area is structurally complex, and the coal-bearing strata dip steeply. A 230 ft shaft was driven along "Big Seam Number II", which was the only coal bed developed in this area. Production prior to 1887 was about 100 tons.

Texas:

Eagle Spring:

References: (continued)

Underwood, J. R., Jr., 1962, Geology of Eagle Mountains and vicinity, Trans-Pecos Texas: University of Texas Austin, Ph.D. dissertation, 560 p.

Rank: Bituminous. High volatile content.

---- 1963, Geology of Eagle Mountains and vicinity, Hudspeth County, Texas: University of Texas, Austin Bureau of Economic Geology Quadrangle Map 26, scale 1:48,000.

During 1896. The area, which is structurally complex, was developed by an adit 100 ft deep, and a 175 ft shaft. Coal in the area is generally 8-10 in. thick, and was most likely deposited in a shallow lagoon or estuary.

Texas:

San Carlos Field

Location: Presidio County, near San Carlos, 21 miles  
NNW of Candelaria.

Age: Late Cretaceous, San Carlos Formation.

Rank: Bituminous. High volatile content.

Comments: The San Carlos Coal Company, which was  
formed in 1893, mined coal for 6 months  
during 1896. The area, which is  
structurally complex, was developed by  
an adit 100 ft deep, and a 175 ft shaft.  
Coal in the area is generally 8-10 in.  
thick, and was most likely deposited in  
a shallow lagoon or estuary.

Texas:

Terlingua Field (Big Bend area)

Location: Brewster County.

Age: Late Cretaceous, Gulfian Series.

Rank: Variable. Unoxidized material from the Chisos mine is subbituminous coal with a high content of moisture, ash, sulfur. Resinous pods are common. Locally, near shallow intrusives, coal is anthracite.

Comments: Coal beds generally range from a few inches to 3 ft in thickness. Maximum bed thickness is about 4 ft. Coals are locally associated with carbonaceous shale sections 20 ft thick. Coals were probably formed in coastal swamp deposits. The Chisos Mining Company attempted to mine coal in this area during the 1930's and 1940's; however, no production information is available.

Utah:

## Coalville Field

Location: Summit, Salt Lake Counties.

Age: Cretaceous. Spring Canyon Member and Coalville Member, Frontier Formation, and Dry Hollow Member, Wanship Formation.

Rank: Subbituminous. Low ash, moderate sulfur content.

Comments: The extreme western extension of the Coalville field lies within the project study area. The Cretaceous rocks may be coal-bearing in the area shown on the accompanying map.

The principal mining activity in the area has occurred in a small area east of Coalville, where Cretaceous rocks are exposed through a window in the Tertiary rocks. The Wasatch coal bed occurs in the Coalville Member of the Frontier Formation, and was the primary mining target with a thickness commonly between 8 and 10 ft. Other beds are too thin to be of economic importance. This coal is of importance only to local markets.

Utah:

Goose Creek Creek

Location: Box Elder, Utah.

Age: Miocene and Pliocene, Salt Lake Formation;  
Miocene and Pliocene(?), Payette Formation.

Rank: Lignite.

Comments: Lignite has been mined in small quantities for local use from both formations. High ash content. Some uranium mineralization occurs locally in lignite (Idaho, T. 16 S., R. 21 E.) along the flanks and trough of a shallow syncline.

Utah:

Harmony Field

Location: Northern Washington County, southern Iron County.

Age: Late Cretaceous; Dakota Sandstone and Tropic Shale, undivided.

Rank: Variable. Locally metamorphosed to semianthracite.

Comments: At least 6 coal beds are known to occur in the units correlative with the Tropic Shale and Dakota Sandstone. The coal-bearing strata were severely deformed by igneous intrusions in the Pine Valley Mountains. The coal beds, which range from 1 to 7 ft thick, contain a high percentage of ash.

Numerous prospect pits, adits and shafts have been dug, however, production has been insignificant.

Utah:

Kolob Field

Location: Southeast Iron, northeast Washington Counties.

Age: Late Cretaceous. Dakota Sandstone - Tropic Shale undifferentiated unit, Straight Cliffs Formation, Wahweap Formation.

Rank: Subbituminous to bituminous.

Comments: During the early stages of mining, coal was used primarily in local mining districts. Pacific Utilities Company operated a steam plant with local coal between 1948-1969. Coal from the Kolob field is generally of poor quality, and is high in sulfur and ash.

Utah:

Wales Field

Location: Juab, Sanpete Counties.

Age: Paleocene and Late Cretaceous, North Horn Formation.

Rank: Subbituminous.

Comments: The area shown on the accompanying map represents Cretaceous strata that may contain thin coal beds. The productive part of the Wales field lies outside of the project study area. Coal in the Wales field is generally 3 to 4 ft thick, and is overlain and underlain by limestones and oil shale. The coal beds are lenticular, and contain common shale and bony interbeds. The coal is low in moisture and high in ash and sulfur. Mines operated intermittently between 1855 and 1955; however, production was not substantial.
