GEOHYDROLOGIC DATA FOR TEST WELL USW G-4, YUCCA MOUNTAIN AREA, NYE COUNTY, NEVADA

By C. B. Bentley

ABSTRACT

This report presents data on drilling operations, lithology, borehole geophysics, hydrologic monitoring, core analysis, water chemistry, pumping tests, and packer-injection tests for test well USW G-4. The well is one of a series of test wells drilled in and near the southwestern part of the Nevada Test Site, Nye County, Nevada, in cooperation with the U.S. Department of Energy. These test wells are part of the Nevada Nuclear Waste Storage Investigations to identify suitable sites for underground storage of high-level radioactive wastes.

Test well USW G-4 was drilled to a total depth of 915 meters through volcanic rocks, consisting mostly of ash-flow tuff. Depth of water in the well during drilling and testing ranged from 538 to 544 meters below land surface. Static water level after completion of drilling was at an approximate altitude of 730 meters above sea level. Drawdown in the well was about 3 meters after test pumping more than 5,000 minutes at a rate of 16 liters per second. A borehole-flow survey indicated that almost all water withdrawn from the well was contributed by the zone between a depth of about 865 and 915 meters below land surface. A composite water sample collected after well completion contained 216 milligrams per liter of dissolved solids, with relatively large concentrations of silica, sodium, and bicarbonate.
INTRODUCTION

The U.S. Geological Survey has been conducting investigations at Yucca Mountain, Nevada, to evaluate the hydrologic and geologic suitability of the site for storing high-level nuclear waste in an underground mined repository. These investigations are part of the Nevada Nuclear Waste Storage Investigations being conducted in cooperation with the U.S. Department of Energy, Nevada Operations Office. Test drilling has been a principal method of investigation. This report presents geohydrologic and drill-hole data from test well USW G-4.

Test well USW G-4 is located in Nye County, Nevada, about 140 km northwest of Las Vegas, in the southern part of the State (fig. 1). The well is near the base of the slope between the forks of a wash on the east flank of Yucca Mountain (fig. 2). Location of the site is Nevada State Coordinate System Central Zone N 765, 807 and E 563, 082. Altitude of the land surface at the well site is 1270.0 m above sea level.

DRILLING OPERATIONS

Drilling of test well USW G-4 started on August 22, 1982, and was continuously cored below a depth of 12 m. Total depth of 915 m was reached on November 7, 1982, and reaming to allow for hydrologic testing was completed on November 29, 1982. The rotary drilling fluid was air foam consisting of air, detergent, and water. Maximum deviation was 9.5° from vertical. Well construction is shown in figure 3. Detailed drilling history is contained in the files of the engineering consulting firm, Fenix and Scisson, Inc., Las Vegas, Nevada.

LITHOLOGIC SAMPLING AND WELL LOGGING

Lithologic Log

The lithology penetrated by test well USW G-4, as determined from rock-bit cuttings and core, is presented in table 1. Ash-flow tuff is the predominant rock type. Thin beds of air-flow tuffs have various degrees of welding, alteration, and zeolitization induration. In the remainder of the report, shortened names of stratigraphic units are used. For the complete designation of formation and member, see table 1.

Paintbrush Tuff of Tertiary age

Tiva Canyon Member

Tuff, ash-flow, grayish-red, densely welded, devitrified; pumice, grayish-red, medium gray, devitrified; 2 percent phenocrysts (sanidine); rare very-light-gray rhyolitic lithic fragments; occasional lithophysal cavities (open and flattened), in upper 12 m. 17.5 24.2

Tuff, ash-flow, pale-brown, pale-red, moderately to densely welded, devitrified; pumice, pale-red, brownish gray, devitrified with sparse to abundant moderate reddish-orange pumice altered to smectite (swelling) clay; less than 2 to 4 percent phenocrysts (sanidine and plagioclase); rare very-light-gray to medium-light-gray rhyolitic lithic fragments, commonly less than 5 mm in size. 11.8 36.0

Tuff, ash-flow, dark-yellowish-orange, partially-to-nonwelded, vitric; pumice, grayish-orange-pink, vitric and argillic(?); 1 to 2 percent phenocrysts (sanidine and plagioclase); abundant black and very yellowish-orange glass shards. 6.1 42.1

Bedded tuff, ash-fall, light-brown, moderately indurated, vitric, abundant moderate-orange pink pumice (vitric, argillic) and black glass shards; 2.4 m of core lost, of which part may be from subsequent unit. 3.0 45.1

Yucca Mountain Member

Bedded tuff, ash-fall, bedded, reworked, pale-yellowish-brown, light-olive-gray, light-brown, slightly indurated, vitric, beds predominantly composed of light-olive-gray vitric pumice and black glass shards, rare light brownish-gray

1 Depth to bottom of individual interval and total depth are accurate only to the nearest meter, but are reported to tenths of a meter to agree with thickness of individual units. Total depth probably is 915 meters ± 0.5 meter.
Geophysical Well Logs

Geophysical logs were run in test well USW G-4 to define lithology, correlate with logs of nearby wells, collect data on porosity and fractures, obtain fluid levels, and gage the diameter of the well. Geophysical logs also were used to help select intervals for hydraulic testing. A summary of geophysical logs made in this well for testing purposes, and the intervals logged are listed in table 2.

Geophysical logs that can be related directly to water-yielding zones include: (1) The self-potential curve on electric logs; (2) the optical television log that shows water seeps above the water table and low-angle fractures in the water-yielding zone; and (3) the temperature log where the thermal gradient changes opposite water-yielding zones.

Hydrologic Properties of Core Samples

More than 350 vertical core samples were taken between depths of 12 and 915 m (total depth) from test well USW G-4. Core samples from selected intervals have been sent to the U.S. Geological Survey laboratory, and Holmes and Narver Materials Testing Laboratory for determining porosity, density, pore saturation, and other physical properties. Results of these laboratory analyses are not yet available.

Water Levels

Water-level observations and measurements in test well USW G-4 were made during and after the drilling as part of hydraulic tests, for the purpose of: (1) Locating any perched-water zones above the water table; (2) identifying the depth at which ground-water saturation occurs; (3) determining the composite hydraulic head in the well; and (4) identifying hydraulic heads in various water-bearing zones. Water-level measurements are listed in table 3.

HYDROLOGIC TESTING AND WATER SAMPLING

Pumping Tests

Drawdown and recovery tests were made in conjunction with two pumping periods after test well USW G-4 had been drilled to its total depth, cased to 615 m, and perforated below 549 m. Pumping-test information is given in table 4. Data plots of these tests are shown in figures 4 through 7. Drawdown-test data were plotted using drawdown versus time after start of pumping as the coordinates. Recovery-test data were plotted with recovery against time after pumping stopped as the coordinates.

Borehole-Flow Survey

A borehole-flow survey with radioactive iodine-131 as a tracer was used to measure vertical flow of water in the well bore, while water was being pumped from the well. The tracer was released into the well at selected depths and tracked past two gamma detectors to determine velocity of the water. Velocity, multiplied by the cross-sectional area of the hole determined from caliper logs, defined the rate of flow in the well at a given depth. The borehole-flow survey in test well USW G-4 was made during the drawdown phase of pumping test 2. Results of the survey are shown in figure 8.

Packer-Injection Tests

Packer-injection tests were made, using inflatable packers to isolate test zones for intervals where hole-size and configuration allowed setting the packers. Intervals tested are listed in table 5. Water was injected into the interval between two packers, or between one packer and the bottom of the hole. The decline of hydraulic head with time was monitored in the isolated interval. Thirteen tests were made in test well USW G-4 for the intervals between 615 and 915 m (total depth). Injection curves are plotted in figures 9 through 21. The ratio of hydraulic head at time after injection started ($H_t$) to hydraulic head ($H_0$) at time of injection is plotted against time after injection started.

Chemical Analysis of Water

A composite water sample was collected for chemical analysis from test well USW G-4 near the end of the first pumping test; results of the analysis are shown in table 6.
