INTRODUCTION

In March of 1984 a reconnaissance geochemical survey was made in the Jayaco Concession Area, Dominican Republic. This reconnaissance survey was carried out by scientists from the U. S. Geological Survey and from the Direccion General de Mineria e Hidrocarbvuros. Upon Completion the results were forwarded to the Director General of the Direccion General de Mineria e Hidrocarburos.

The Study area was bounded north-south by 19 50'00" and 19 10'00" and east-west by 70 24'50" and 70 36'54" and included the town of Bonao on the eastern edge.

GEOLOGIC SETTING

Most of the study area is underlain by the Tireo and Duarte Formations of Bowin (1966). Observations made during this study indicate that the area of each formation consists of rocks which are dissimilar or even unrelated, and the term "terrane" is used in this report to indicate this variability.

The highest areas and steepest slopes, in the southern part of the area , are underlain by Tireo terrane, which consists mostly of volcanic, pyroclastic, and volcanogenic sedimentary rocks of intermediate composition.

The Duarte terrane forms much of the northern and southeastern parts of the area. In the study area this consists largely of the upper portions of an ophiolite (here called Rio Camu ophiolite), modified by later intrusion but otherwise well preserved. Only in the southeastern corner of the study area the Duarte terrane contain the "typical" schistose mafic volcanics. A norite body is also present in the southeastern corner of the area.

The Tireo terrane is separated from The Duarte terrane by the steeply-dipping Bonao Fault zone. Evidence for the existence of a fault zone (based on incompatability of the rocks, not on crushing) is good, but the swing of fault strike through more than 90° (Bowin, 1966) makes the presence of several faults more likely.

Tonalites intrude both the Tireo and Duarte terranes. The northern tonalite is cut by the Bonao Fault.

The Maimon Formation of Bowin (1966) is present in the northeast corner of the Jayaco area, and consists of silicic welded ash-flow tuff that probably was deposited sub-aerially.

Physiography

The study area is in the southeastern end of the Cordillera Central. Mountain slopes range from steep to precipitous with as much as 2000 meters of relief on the eastern and northern sides of the study area. The central part of the study area contains low rolling hills with moderate relief. Most of the study area is highly vegetated with woods and underbrush. Bedrock exposures are mainly confined to the stream beds of the larger streams and rivers and to road cuts. There are few roads in the study area, but numerous foot trails exist and these provide the main access. Major rivers cut the study area and most trend north-south. The Rio Blanco in the southern part of the study area is an ecception to this and flows east-west.

METHODS OF STUDY

Sample Collection

Stream sediment samples were collected from first and second order stream drainages at a sample density of approximately 1 sample per 2.5 sq km, representing drainage areas as large as 10 sq km. In this study it was only possible to sample stream drainages that were readily accessable and as a result only about 60 to 70 percent of the total area was sampled. All of the 69 stream sediment samples taken in this study were from active streams. The samples were collected perpendicular to the flow direction across the full width of the active stream channel in order to obtain an unbiased sample. The stream sediment samples were sieved on site through a 2 mm stainless steel screen, placed in a 11 X 14 cm cloth bag, and air dried.

Panned concentrate samples were taken at each stream sediment sample site. The panned concentrate samples were purposefully biased by collection from points of natural concentration of heavy minerals by stream processes. When collecting panned concentrate samples, sufficient material was sieved through a 2 mm stainless steel screen to fill a 24 cm diameter gold pan. The samples were then panned by hand at the sample site to approximately 1/100 of their original volume (approximately 115 g) and placed in 6 X 18 cm paper bags. All panned concentrate samples were air dried.

Rock samples were collected from outcrops or exposures in the vicinity of the plotted site location. Most samples were taken from areas of observed or suspected mineralization including any mines, mine dumps, or prospect pits. Altered areas and geologic structures were also sampled where observed. Most of the rock sampling was at widely spaced intervals, but close spaced sampling was done along the Bonao-Constanza road near the crest of the mountain range in the central part of the area.

Soils were taken at close spaced intervals in two areas along the Bonao-Constanza road, near the crest of the mountain range.

Sample Preparation

Stream Sediments, Rocks, and Soils -- Dried stream sediment samples were sieved through a 0.177 mm stainless steel sieve and the -0.177 mm fraction was ground to a powder for analysis. Rock and soil samples were crushed and then pulverized with ceramic plates to minus 0.15 mm.

Concentrate Samples -- The dried panned concentrate samples were seived through a 0.590 mm stainless steel sieve and the +0.590 mm fraction was discarded. The -0.590 mm fraction was further concentrated by flotation of the low density minerals (specific gravity 2.86) in bromoform. The remaining high density fraction was separated into three fractions based on degree of magnetism. After removal of magnetite by a hand magnet, the next most magnetic fraction was separated by passing the sample through an electromagnetic separator set at 0.6 amp. The intermediate fraction was separated by again passing the sample through an electromagnet, this time at setting of 2.0 amps. The resulting nonmagnetic heavy-mineral fraction at 2.0 amps was examined under a binocular microscope for mineralogy and ground to a powder for analysis.

Sample Analysis

Spectrographic Method

Following preparation, the stream sediment, rock, and soil samples were analyzed by a semiquantitative emission spectrographic method described by Grimes and Marranzino (1968) for the analysis of geologic materials. Spectrographic results were obtained by visual comparison of spectra derived from the unknown against spectra obtained from standards made from pure oxides or carbonates based on a 10 mg sample weight using a 20X comparator. Standard concentrations are geometrically spaced over any given order of magnitude of concentration and are prepared in such a way that a range of concentrations normally found in naturally occurring samples are bracketted. When comparasions are made with sample films for semiquantative use, reported values are rounded to 100, 50, 20, 10, and so forth. Those samples whose concentrations are estimated to fall between the above values are given values of 70, 30, 15, 7, and so forth (Grimes and Marranzino, 1968). The precision of the method is approximately plus or minus one reporting unit at the 83 percent confidence level and plus or minus two reporting units at the 96 percent confiedenc level (Motooka and Grimes, 1976). Values determined for the major elements (magnesium, calcium, iron, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram). Table 1 lists all elements analyzed and their lower limits of determination.

Following preparation, the nonmagnetic heavy-mineral-concentrate samples were analyzed by a modified version of semiquantitative emission spectrographic method described by Grimes and Marranzino (1968) for the analysis of geologic materials. Because the nonmagnetic heavy-mineral-concentrate samples contain mineral species often high in iron, titanium, calcium, and zirconium the following modification was made to eliminate the spectral interferences produced by high concentrations of these elements. Five milligrams of prepared sample were mixed with 25 milligrams of a 4:1 mixture of pure graphite powder and pure Arkansas quartz. This mixture was packed into a preformed graphite electrode and arced under the same conditions as were the stream-sediment samples. Because the initial sample weight was half that used to produce the standard spectra, all values were increased by two reporting intervals or steps (e.g. 20 ppm reported as 50 ppm) Similarly the lower limits of detection also were doubled (table 2). Spectrographic results were obtained by visual comparison of spectra derived from the unknown against spectra obtained from standards made from pure oxides or carbonates using a 20x comparator. Standards were prepared so that their concentrations encompass those in natural material. When comparisons are made with sample films for semiquantitative use, reported values are rounded to 100, 50, 20, 10, and so forth. Those samples whose concentrations are estimated to fall between the above values are arbitrarily given values of 70, 30, 15, 7, and so forth (Grimes and Marranzino, 1968). The precision of the method is approximately plus or minus one reporting unit at the 83 percent confidence level and plus or minus two reporting units at the 96 percent confidence level (Motooka and Grimes, 1976). Values determined for the major elements (magnesium, calcium, iron, and titanium) are given in weight percent; all others are given in parts per million (micrograms/gram). Table 2 lists all elements analyzed and their lower limits of determination and the results of these analyses for 31 elements are given in table 5, columns 4-34.

TABLE 1.--Limits of determination for the spectrographic analysis of stream sediment and rocks and soils based on a 10 mg sample for samples from the Jayaco Concession Area, Dominican Republic.

All analytical results, sample descriptions, and locations were entered into a computerized rock analyses storage system (RASS) (VanTrump and Miesch, 1977).

Chemical Methods

In addition to the semiquantative spectrographic analyses the rock and soil samples were analyzed for 10 elements by various wet chemical methods. Table 3 lists the elements analyzed, the methods, the determination limis, the analyst, and the reference for the method used.

Table 3.--Summary of elements analyzed, analytical method, lower limits of detection, analyst, and analytical reference for samples from the Jayaco Concession Area, Dominican Republic.

Element or constituent determined	Analytical Method	Determination limit[1] (micrograms/ grams or ppm	Analyst	Reference
Gold (Au)	Atomic Absorption	0.05	T. A. Roemer and Sharkey	Thompson and J. others, 1968
Mercury (Hg)	Instrumental (Jerome)	0.02	.....Do.....	Modification of McNerney and others, 1972 and Vaughn and McCarthy, 1964
Arsenic (As)	Colormetric	10.0	.....Do.....	Ward, 1963
Antimony (Sb)	Atomic Absorption	2.0	.....Do.....	Welsch, 1975
Zinc (Zn)	.....Do.....	5.0	.....Do.....	Modification of Viets, 1978
Bismuth (Bi)	.....Do.....	1.0	.....Do.....	.....Do.....
Cadmium (Cd)	.....Do.....	0.05	.....Do.....	.....Do.....
Copper (Cu)	.....Do.....	5.0	.....Do.....	.....Do.....
Lead (Pb)	.....Do.....	5.0	.....Do.....	.....Do.....
Silver (Ag)	.....Do.....	0.05	.....Do.....	.....Do.....

1/The determination limit is dependent upon sample weight. Given limits imply use of sample weight required by method. Higher limits of determination result from using less than required sample weight.

RASS

Upon completion of all analytical work, the geological and analytical data fro the samples was entered into a computer-based file called RASS (Rock Analysis Storage System). Any or all of this information may be retrieved and converted to a standard form (STATPAC) for computerized statistical analysis or publication (VanTrump and Miesch, 1976)

DESCRIPTION OF DATA TABLES

Tables 4, 5, and 6 list the analyses for the stream sediment, panned concentrate, and rock or soil samples. For the tables, the data are arranged so that column 1 contains the USGS-assigned sample numbers. These numbers correspond to the numbers shown on the site location map (plate 1). Duplicate numbers indicate more than one sample taken at a site. Columns in which the element headings show the letter "s" below the element symbol are emission spectrographic analyses; an "aa" indicates atomic absorption analyses. A letter "N" in the tables indicates that a given element was looked for but not detected at the lower limit of determination shown for that element shoen in tables 1, 2, and 3. If an element was observed but was below the lowest reporting value, a "less than" symbol (<) was entered in the tables in front of the lower limit of determination. If an element was observed but was above the highest reporting value, a "greater than" symbol (>) was entered in the tables in front of the upper limit of determination.

In the table for the rock data (table 6), each analysis is followed by a brief description of the rock or soil sample

Table 6.--Spectrographic, atomic absorption analyses, and descriptions, of rock samples from the Jayaco Concession Area, Dominican Republic

[N, not detected; <, detected but below the limit of determination shown; >, determined to be greater than the value shown.]

Sample	LATITUDE	LONGITUD	
			Samples from the Bonao quadrangle--continued
ABNR0009	18 51 46	70 27 3	Pyrite bearing granodiorite
ABNR0013	18 50 20	70 29 21	Pyritic chert
ABNR0014	18 51 15	70 29 7	Tireo formation, meta-volcanic
ABNR0015	18 51 17	70 29 13	Tireo formation, meta-volcanic
EBNR0010	18 51 38	70 27 3	Fault gouge with secondary copper
EBNR0010	18 51 34	70 27 12	Duarte formation, meta-volcanic
EBNR0021	18 52 13	70 28 36	Quartz latite in Tireo formation
EBNR0022	18 52 3	70 28 55	Tireo formation, pyrite bearing meta-volcanic in shear zone
EBNR0022	18 52 3	70 28 54	Tireo formation, red shale
EBNR0024	18 53 20	70 28 0	Tireo formation, green pyrite bearing meta-volcanic
EBNR0024	18 53 14	70 27 52	Tireo formation, meta volcanic
EBNR0026	18 54 10	70 27 26	Tireo formation, metatuff, semischistose
EBNR0042	18 52 22	70 28 42	Tireo formation, meta volcanic
EBNR0060	18 52 42	70 29 30	Tireo formation, gossan in conglomerate
			Samples from the Constanza quadrangle--continued
CCNR0009	18 59 55	70 34 6	Granodiorite, weathered
CCNR0010	19 57 2	70 37 11	Mafic rock
			Samples from the Fantino quadrangle--continued
AFTR0004	19 1 10	70 27 37	Tireo formation, vesicular meta-andesite
CFTR0006	19 4 23	70 29 45	Mafic meta-volcanic
CFTR0007	19 3 50	70 28 47	Mafic meta volcanic
DFTR0007	19 1 50	70 28 52	Tireo formation, andesite or quartz porphyry
DFTR0009	19 1 30	70 28 37	Tireo formation, green tuff
DFTR0013	19 1 42	70 28 23	Tireo formation, laminated chert, conglomeratic
DFTR0004	19 1 52	70 29 17	Tireo formation, lapili tuff
DFTR0005	19 1 56	70 29 7	Tireo formation, shear zone in meta-volcanic
DFTR0006	19 2 0	70 29 5	Tireo formation, lapili tuff
EFTR0007	19 2 7	70 29 51	Tireo formation, pyritic lapili tuff
EFTR0008	19 7 6	70 32 7	Shear zone in peridotite
EFTR0011	19 8 10	70 26 0	Maimon formation, laminated vitric ash-flow tuff
EFTR0014	19 7 8	70 26 48	Maimon formation, laminated vitric ash-flow tuff
EFTR0015	19 9 38	70 29 18	Maimon formation, shear zone in diabase with talc
			Samples from the Jarabacoa quadrangle--continued
AJBR0033	19 8 44	70 35 46	Quartz vein in saprolite
AJBR0035	19 6 36	70 33 36	Pyroxenite
AJBR0056	19 1 36	70 30 40	Tireo formation, quartz vein with secondary copper
AJBR0059	19 1 36	70 30 40	Tireo formation, wall rock near quartz vein, secondary copper
AJBR0060	19 1 36	70 30 40	Tireo formation, gossan from quartz vein
