CONVERSION FACTORS

The inch-pound units used in this report may be converted to SI (International System) units by using the following conversion factors:

Multiply inch-pound units	*By*	*To obtain metric units*
acre-foot (acre-ft)	0.001233	cubic hectometer
cubic foot per second (ft^3/s)	0.2832	cubic meter per second
square mile (mi^2)	2.590	square kilometer
ton, short, per acre-foot (ton/acre-ft)	1.119	kilogram per cubic hectometer
ton, short, per day (ton/d)	907.2	kilogram per day

Degree Celsius (°C) may be converted to degree Fahrenheit (°F) by using the following equation:

$$°F=9/5°C+32$$

The following terms and abbreviations also are used in this report:

microgram per liter (µg/L)
microsiemens per centimeter (µS/cm)
milligram per liter (mg/L)

SELECTED TRACE-ELEMENT DATA FOR STREAMS IN THE SOUTHERN YAMPA RIVER BASIN, NORTHWESTERN COLORADO

By Wendy S. Maura

ABSTRACT

Increases in coal mining in northwestern Colorado have increased concerns about the impact of mining on the chemical quality of surface water. An area of particular concern is in the southern part of the Yampa River basin. To identify the changes produced by mining in this area, it is necessary to determine the present water chemistry resulting from the geology, climate, and land use. Because few data were available, a program for the synoptic collection of water-quality data was developed, in which sampling sites were selected to determine the surface-water chemistry.

This study was begun in April 1982. Water-quality samples were collected from sites on continuously flowing streams where a large concentration of suspended material was present. Each selected site, from the Oak Creek drainage near Steamboat Springs on the east, to the surface-water gaging station on the Yampa River near Maybell on the west, was sampled repetitively as changes occurred in discharge and specific conductance. Water-quality data from surface-water gaging stations and other selected surface-water sampling sites in the study area for water years 1976 to 1982 are included in the report.

INTRODUCTION

Increasing demands for energy have resulted in a significant increase of coal production in Colorado, particularly in the Yampa River basin of northwestern Colorado. This development has increased concerns about the impacts of mining on the quality of surface water. To identify the possible changes in water quality produced by mining in this area, it is first necessary to determine the present water chemistry resulting from the geology, climate, and land use. A synoptic water-quality program was developed to assess the water chemistry of the Yampa River basin.

This study began in April 1982, in cooperation with the U.S. Bureau of Land Management. It was a continuation of a 1981 study (Maura, 1982) in which water-quality samples were collected to determine concentrations of the major dissolved constituents present in streams of this study area. The objective of this report is to make available the trace-element data collected for selected streams in this study area.

DESCRIPTION OF STUDY AREA

Data presented in this publication were collected from some of the sites sampled in the 1981 study (Maura, 1982). In that study, 26 sites were sampled

in the synoptic data-collection program. The criterion for selecting a stream for sampling was that the stream be flowing in April 1981.

In this study, 18 sites were chosen from the original 26 to collect trace-element data. The reduced number of sites results from an additional criterion that a site must have a large concentration of suspended material. In addition to these 18 sites sampled during the study period, 18 established surface-water gaging stations were selected that had similar trace-element data available. Locations of these established surface-water gaging stations and additional surface-water sampling sites are shown in figure 1.

The area of data collection was the southern part of the Yampa River basin between the confluence with Oak Creek upstream from Steamboat Springs, downstream to the surface-water gaging station, 09251000 Yampa River near Maybell. This downstream station was chosen as the western limit of the study area because it is included in the National Stream Quality Accounting Network (NASQAN), and it is a station for which a large number of water-quality analyses are available.

DESCRIPTION OF DATA

At each study site, water samples were collected as discharge decreased through the season. As flow decreased, suspended-sediment concentration generally decreased. When the sediment concentration was less than 100 mg/L, data collection was discontinued at the site.

The instantaneous discharge of the stream was measured at the time of each sample collection, and the onsite measurements of water temperature, pH, and specific conductance were recorded. Analyses of the water-quality samples were performed at the Denver Central Laboratory of the U.S. Geological Survey, Arvada, Colo.

The individual trace elements and suspended sediment properties analyzed, with units of measurement, are listed below:

Phosphorus, total (mg/L as P)
Aluminum, (µg/L as Al)
Arsenic, (µg/L as As)
Cadmium, (µg/L as Cd)
Chromium, (ug/L as Cr)
Cobalt, (µg/L as Co)
Copper, (µg/L as Cu)
Iron, (µg/L as Fe)
Lead, (µg/L as Pb)
Manganese, (µg/L as Mn)
Mercury, (µg/L as Hg)
Selenium, (µg/L as Se)
Zinc, (µg/L as Zn)
Sediment, suspended (mg/L)
Sediment, discharge, suspended (ton/d)

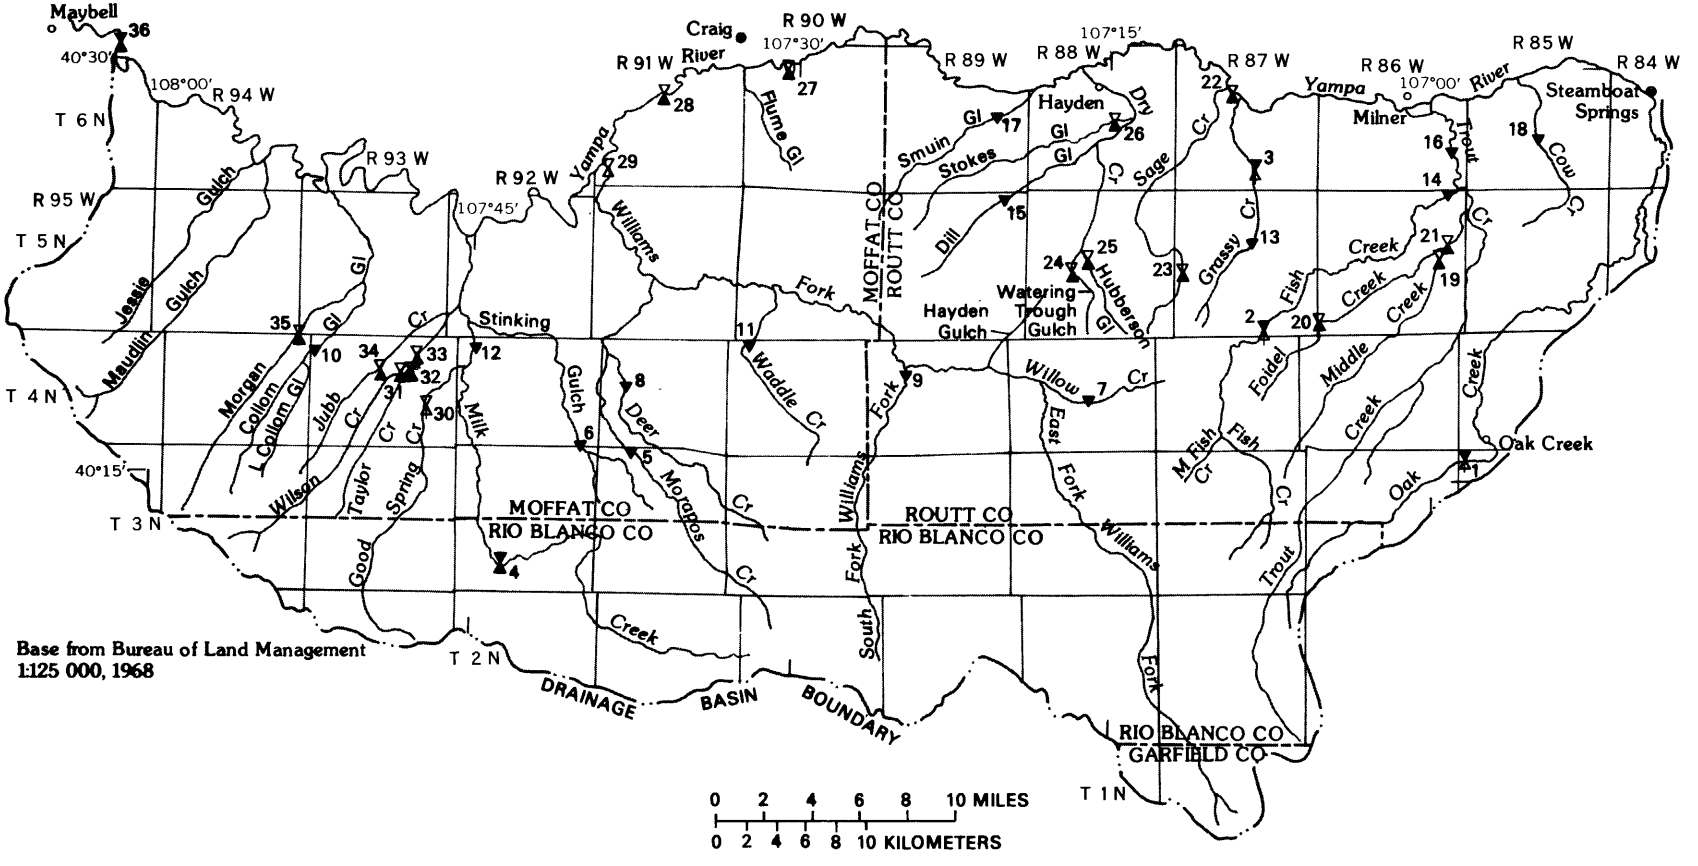

Figure 1.--Location of surface-water gaging stations and selected surface-water sampling sites in the study area.

These trace elements (except phosphorus) were analyzed for total, dissolved, and suspended concentrations.

The location of each water-quality sampling site is shown in figure 1, and a description of each site is given in table 1. Surface-water gaging stations in the study area where both sediment and water-quality data were already available are described in table 2. There are additional surface-water gaging stations in the study area that are not listed in table 2 or shown in figure 1 because they record only streamflow. Many stations listed in table 2 are on the main stem of the Yampa River or its principal tributary, the Williams Fork. These stations are part of the long-term gaging network of the U.S. Geological Survey. Many of the surface-water gaging stations on the smaller tributaries in the study area were operated in cooperation with U.S. Bureau of Land Management as part of the U.S. Geological Survey Coal Hydrology Program.

Data collected at the study sites are listed in table 3. Water-quality constituents and properties determined from samples collected at U.S. Geological Survey surface-water gaging stations are listed in table 4. Data are listed only for the same constituents collected at the study sites. Water-quality data collected prior to water year 1976, and for additional water-qualty constituents, are available for some of these stations and are published annually in a series of the U.S. Geological Survey water-data reports entitled "Water Resources Data--Colorado."

A statistical summary of the constituents reported in tables 3 and 4 is given in table 5. This table contains a summary for six surface-water gaging stations located on the Yampa River, the Williams Fork, and Good Springs Creek. Many samples were collected at these six stations; therefore, only a summary of the data is given, which includes the number of samples, the mean, the standard deviation, and the range of each constituent for the period of record. The actual data are stored in WATSTORE, the U.S. Geological Survey's national water data storage and retrieval system.

ABBREVIATIONS AND SYMBOLS

The following abbreviations and symbols are used in tables 1 through 5.

°C is degrees Celsius;
E is estimated;
ft^3/s is cubic feet per second;
µS/cm is microsiemens per centimeter;
mg/L is milligrams per liter;
N is number of water-quality samples;
ND is not determined;
mi^2 is square miles; and
ton/d is tons per day.
