FACTORS FOR CONVERTING INCH-POUND UNITS TO METRIC UNITS

The analyses and compilations used in this report were made in inch-pound units of measurements. Conversion factors for inch-pound units and metric units are listed below. Multiply inch-pound units by the conversion factor to obtain metric units.

Conversion Factors

<u>Inch-pound units</u>	<u>Conversion factor</u>	<u>Metric units</u>
cubic feet per second	0.02832	cubic feet per second
feet per mile	0.1894	meters per kilometer
gallons per minute	0.06309	liters per second
miles	1.609	kilometers
pounds	0.4536	kilograms
square miles	2.59	square kilometers

DATA COLLECTION FOR A TIME-OF-TRAVEL AND DISPERSION STUDY
ON THE COOSA RIVER NEAR CHILDERSBURG, ALABAMA

By Richard A. Gardner

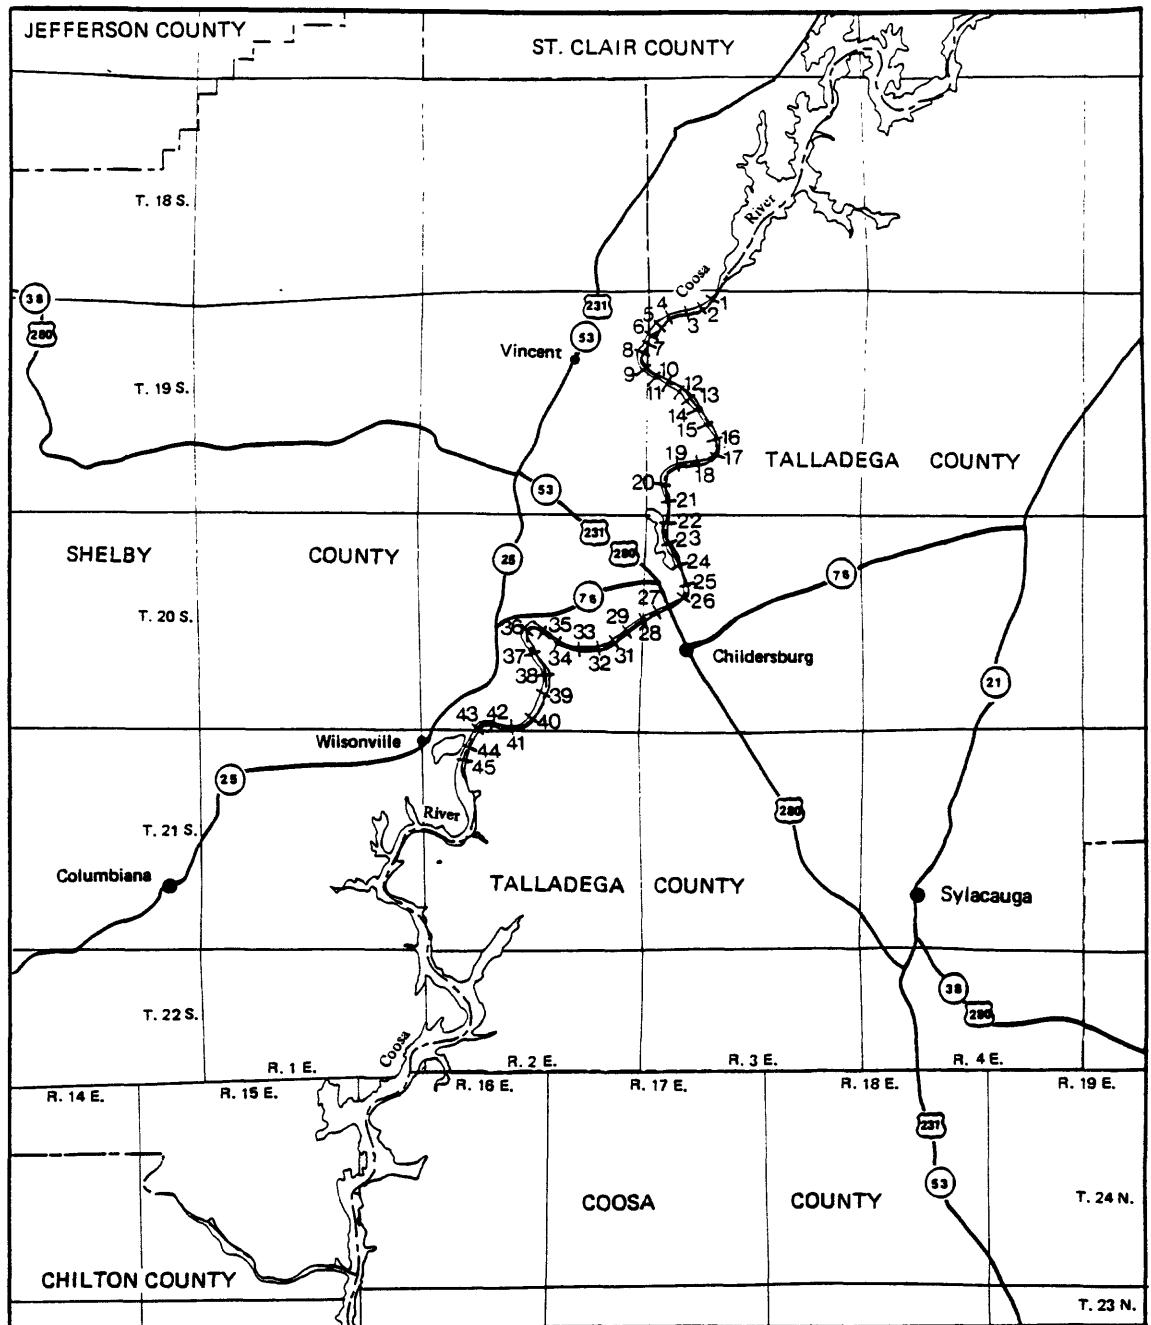

ABSTRACT

Approximately 2,300 dye-tracer samples were collected and analyzed during a five-day time-of-travel study on a 23-mile reach of the Coosa River between Logan Martin and Lay dams near Childersburg, Alabama, October 27 to 31, 1984. Rhodamine WT was used as the tracer-dye. Unsteady flow conditions prevailed in the study reach. The rate of movement of the dye cloud between sampling cross sections ranged from 0.15 to 1.36 feet per second. The average rate of movement of the dye cloud between the injection cross section and the downstream sampling cross section was 0.42 foot per second.

INTRODUCTION

This report describes the data collection phase of a study of the movement of a solute in the Coosa River near Childersburg, Alabama (fig. 1). This study was conducted in cooperation with the Alabama Department of Environmental Management. The study reach is between Logan Martin dam and Wilsonville, Alabama. This reach of the Coosa River is 23 miles long and is in the pool created by Lay dam. The solute used as a tracer for this study was 70 pounds of rhodamine WT dye.

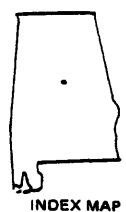

The objective of the study was to simulate the movement of a solute through the 23-mile reach. The information obtained from this study can be used to determine the travel time and pattern of change in concentration of other solutes introduced into the reach at various locations.

DYE INJECTION

The rhodamine WT was mixed with water to provide 360 gallons of a dilute injection solution. The rhodamine WT solution was injected on October 27, 1954, into the Coosa River 0.25 mile downstream of Logan Martin dam. The solution was injected through three orifices, located at the quarter-points of flow in the injection cross section, in order to minimize the length of the mixing reach.

The dilute rhodamine WT was pumped to the three injection points in the cross section at a constant rate of 0.73 gallon per minute. The injection equipment was adjusted so that the rhodamine WT was delivered at an equal rate to each of the three injection points in the injection cross section. Injection of the rhodamine WT began at 0810 hours and ended at 1625 hours on October 27, 1984. The centroid of the rhodamine WT cloud at the injection cross section occurred at 1217 hours, October 27, 1984.

DYE SAMPLING

Forty-five sampling cross sections were established at approximately one-half mile intervals along the 23-mile study reach before the rhodamine WT was injected (table 1 and fig. 1). The top widths of the cross sections were measured instrumentally and the depths of water were measured with recording fathometers. One or more samples were collected at each of these cross sections. Approximately 2,300 samples were collected at these cross sections during the study.

Three sampling procedures were used to monitor and sample the rhodamine WT cloud as it moved downstream. First, grab samples were collected periodically at mid-channel to determine the location of the rhodamine WT cloud and its longitudinal profile. These samples were collected at approximately 1-mile intervals along the reach at the sampling cross sections established for this study.

Three automatic samplers were used to sample the main body of the rhodamine WT cloud at selected sampling cross sections in the reach. Nominal sample intervals ranging from 6 to 120 minutes can be obtained with the samplers used in this study. The actual sampling intervals were determined by observing the operation of the samplers. The nominal sampling interval used for most of this study was 14 minutes. Shorter sampling intervals were used at some cross sections in the early part of the study. The cross sections occupied by the automatic samplers were selected based on analyses of samples collected to determine the longitudinal profile of the rhodamine WT cloud.

Table 1. Location of sampling cross sections in miles downstream of
Logan Martin dam near Childersburg, Alabama

Cross section number	Miles down-stream	Cross section number	Miles down-stream	Cross section number	Miles down-stream
1	0.55	16	7.00	31	14.80
2	1.05	17	7.50	32	15.40
3	1.90	18	7.90	33	16.00
4	2.35	19	8.55	34	16.50
5	2.50	20	9.25	35	17.20
6	2.75	21	9.90	36	17.80
7	3.10	22	10.30	37	18.40
8	3.55	23	10.85	38	19.10
9	4.00	24	11.50	39	19.80
10	4.50	25	12.05	40	20.30
11	5.00	26	12.40	41	20.80
12	5.40	27	13.05	42	21.30
13					
13	5.55	28	13.50	43	21.90
14	5.95	29	13.90	44	22.40
15	6.50	30	14.30	45	22.90

The rhodamine WT cloud was sampled upstream of the automatic samplers at the quarter-points of the channel in order to define the cloud's tail. This sampling was usually started before the arrival of the rhodamine WT cloud and continued until the concentration of the rhodamine WT in the cross section occupied by the automatic samplers had declined to background levels. Grab samples were collected at these sampling points at approximately one-hour intervals.

SAMPLE PROCESSING

The large number of samples collected, and the need for immediate analysis so that subsequent sampling could be scheduled, dictated that a laboratory be located in or near the study area. Therefore, a mobile field laboratory was located near the injection cross section. This laboratory was equipped with a Turner Model 111 filter type fluorometer and the necessary accessory equipment to process the samples using standard fluorometric techniques. Dye standards were prepared from a 3-liter sample of the diluted solution of the rhodamine WT.

As the analyses were performed the data were stored permanently on magnetic media with a microcomputer. The file data for each sample include the cross section location, the location of the sampling point in the cross section, the date of collection, the time of collection, the fluorometer scale settings used for the analysis of the sample and the results of the analysis. Approximately 2,300 samples were analyzed and the results stored with an average turnaround time of less than three minutes.

MOVEMENT OF THE DYE CLOUD

Water samples for tracer-dye analyses were collected at each of the 45 sampling cross sections established in the study reach. The analyses can be used to determine the progress of the tracer-dye as it moves down the reach. Figures 2-5 show the passage of the dye cloud, as defined by increases and decreases in the percent of maximum dye concentration, in selected cross sections in the study reach.

On October 27 and 28 there was no discharge through the turbines at either Logan Martin or Lay dam. There was discharge through the turbines at both these dams for part of the day, each day, October 29-31.

Figure 2 shows the passage of the rhodamine WT cloud at sampling cross section 10, 4.5 miles downstream of Logan Martin dam. The rhodamine WT arrived at this cross section between 0700 and 0800 hours on October 28 almost 24 hours after the start of the rhodamine WT injection. Rhodamine WT concentrations remained low at this cross section until about 1830 hours on October 28. A slow, erratic increase in the concentration of rhodamine WT began at that time. The rhodamine WT concentrations at the right and mid-channel sampling points in this cross section reached their maximum values about 0700 hours October 29. The maximum rhodamine WT concentration at the left sampling point in this cross section occurred about two hours later.

Maximum rhodamine WT concentrations occurred at sampling cross section 15, 6.5 miles downstream of Logan Martin dam, before noon on October 29 (fig. 3) and around 1800 hours the same day at cross section 27, 13.05 miles downstream of Logan Martin dam. The rhodamine WT cloud passing these cross sections is much less dispersed than the cloud passing sampling cross section 10.

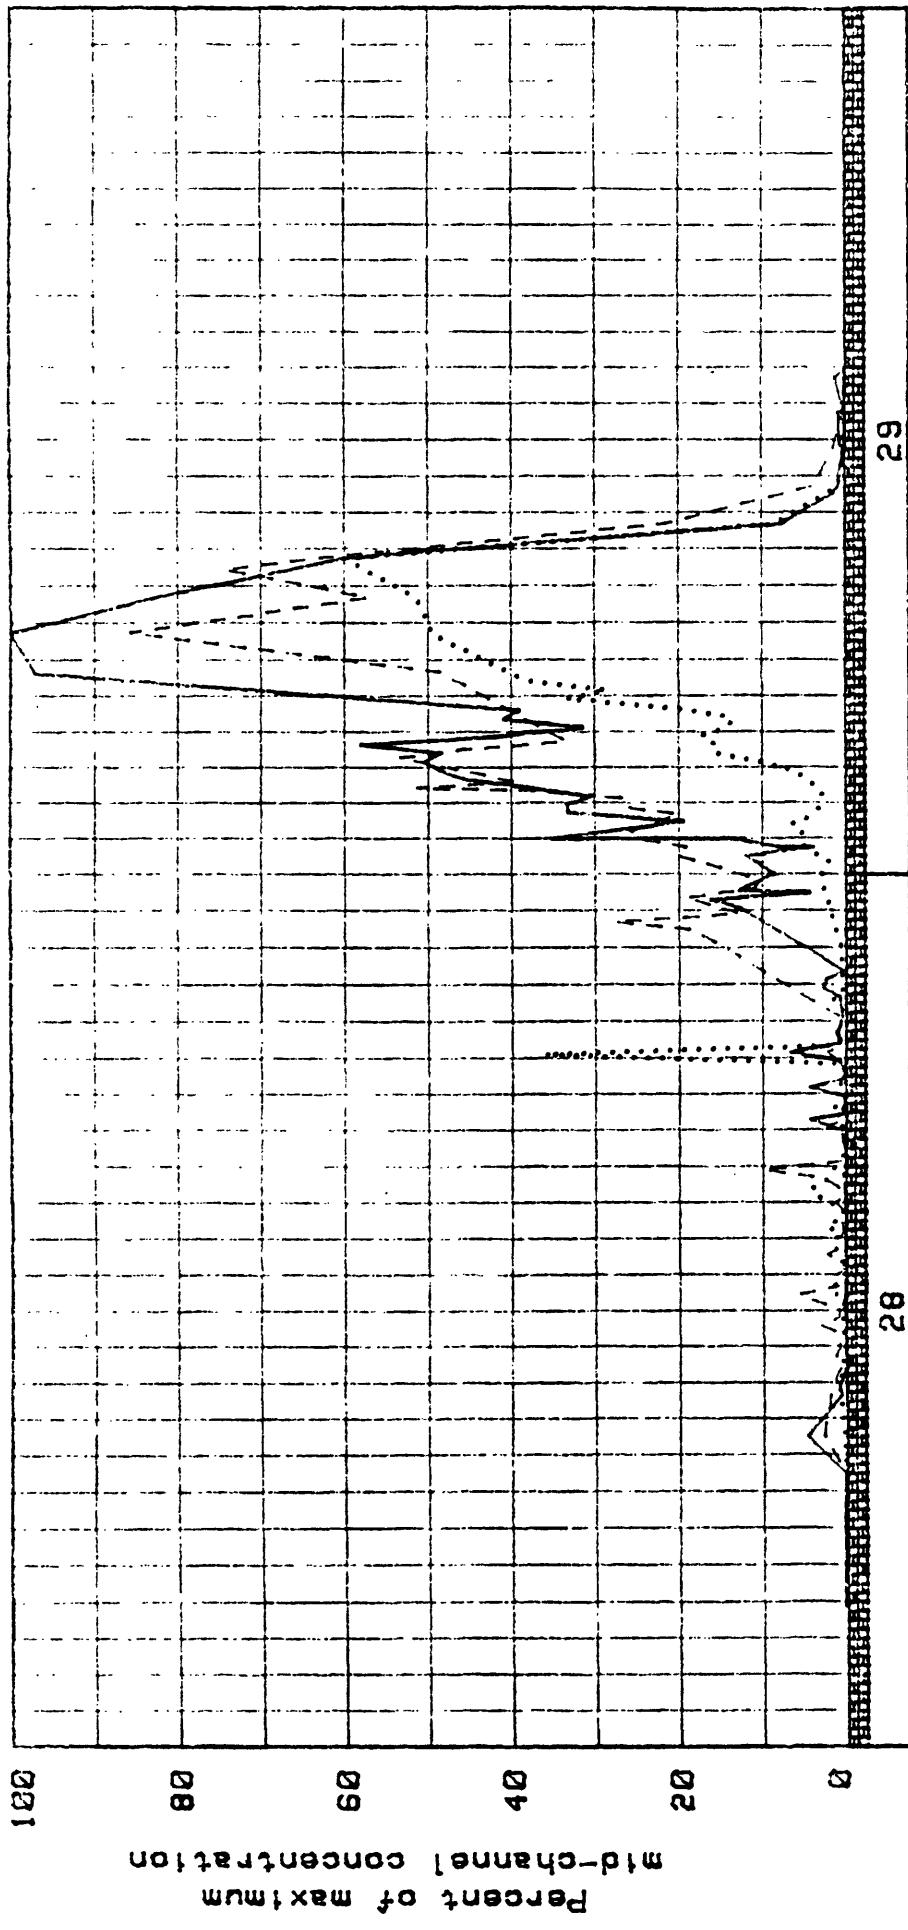

Figure 2. Graph of dye cloud at sampling cross section 10.

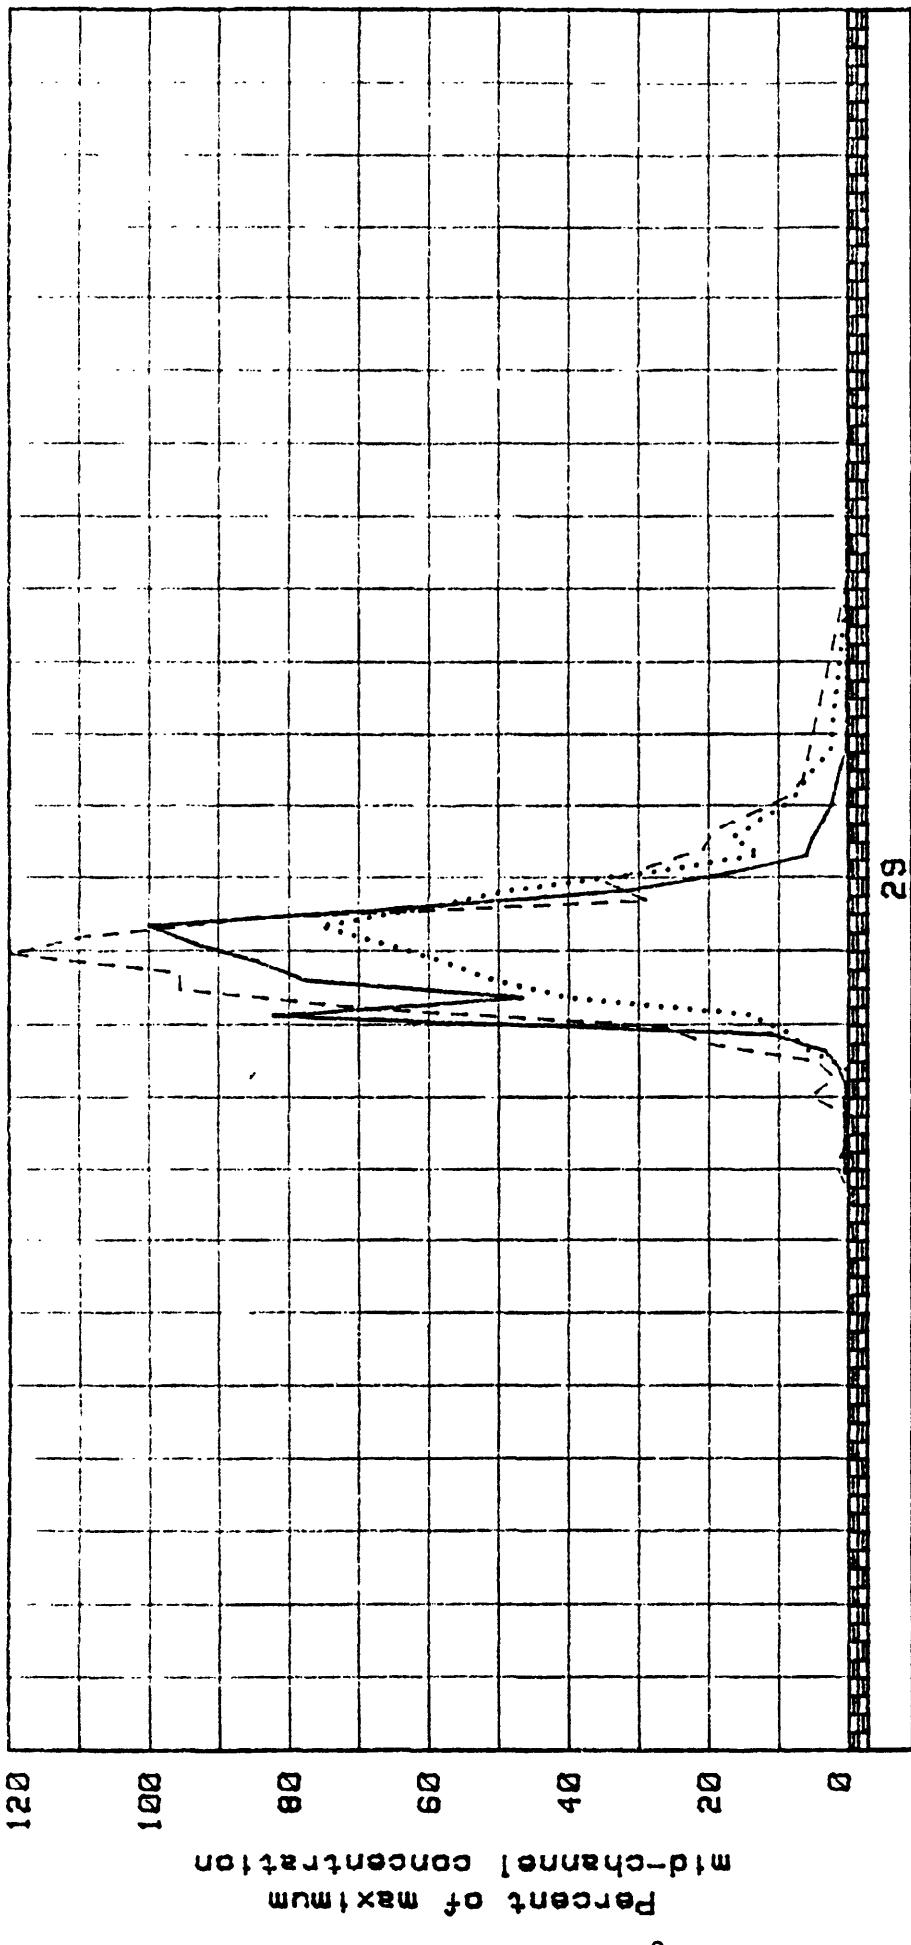

Figure 3. Graph of dye cloud at sampling cross section 15.

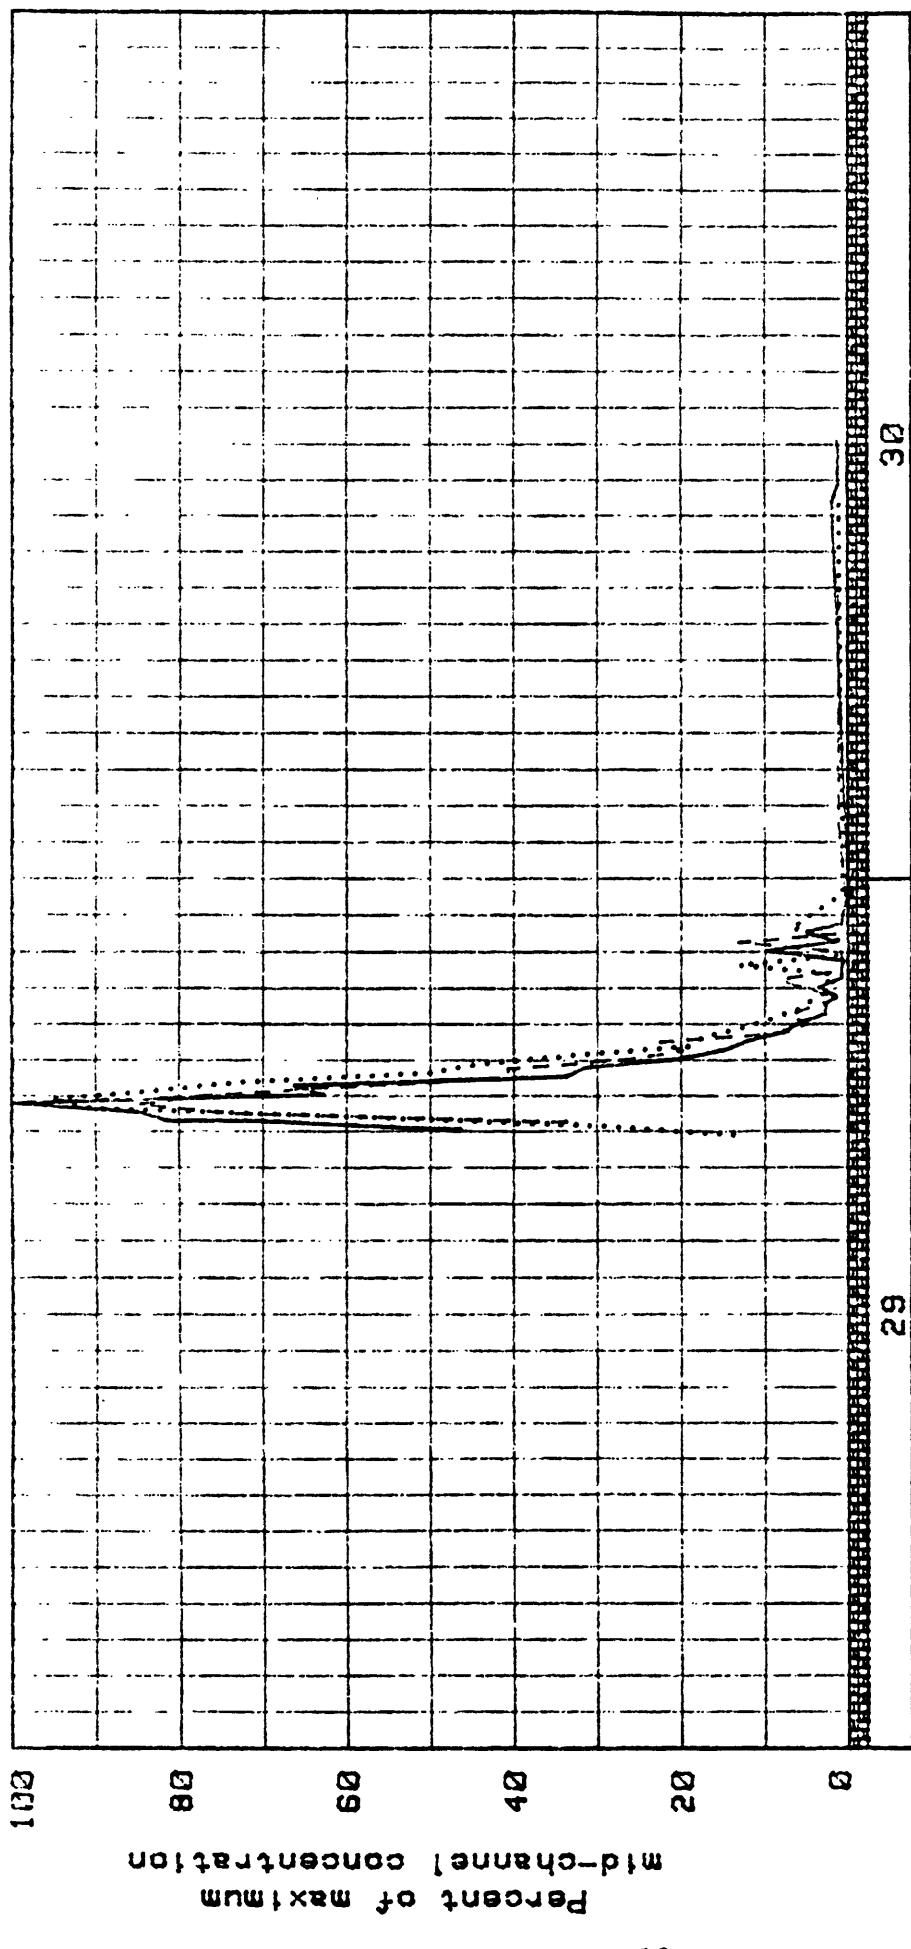

Figure 4. Graph of dye cloud at sampling cross section 27.

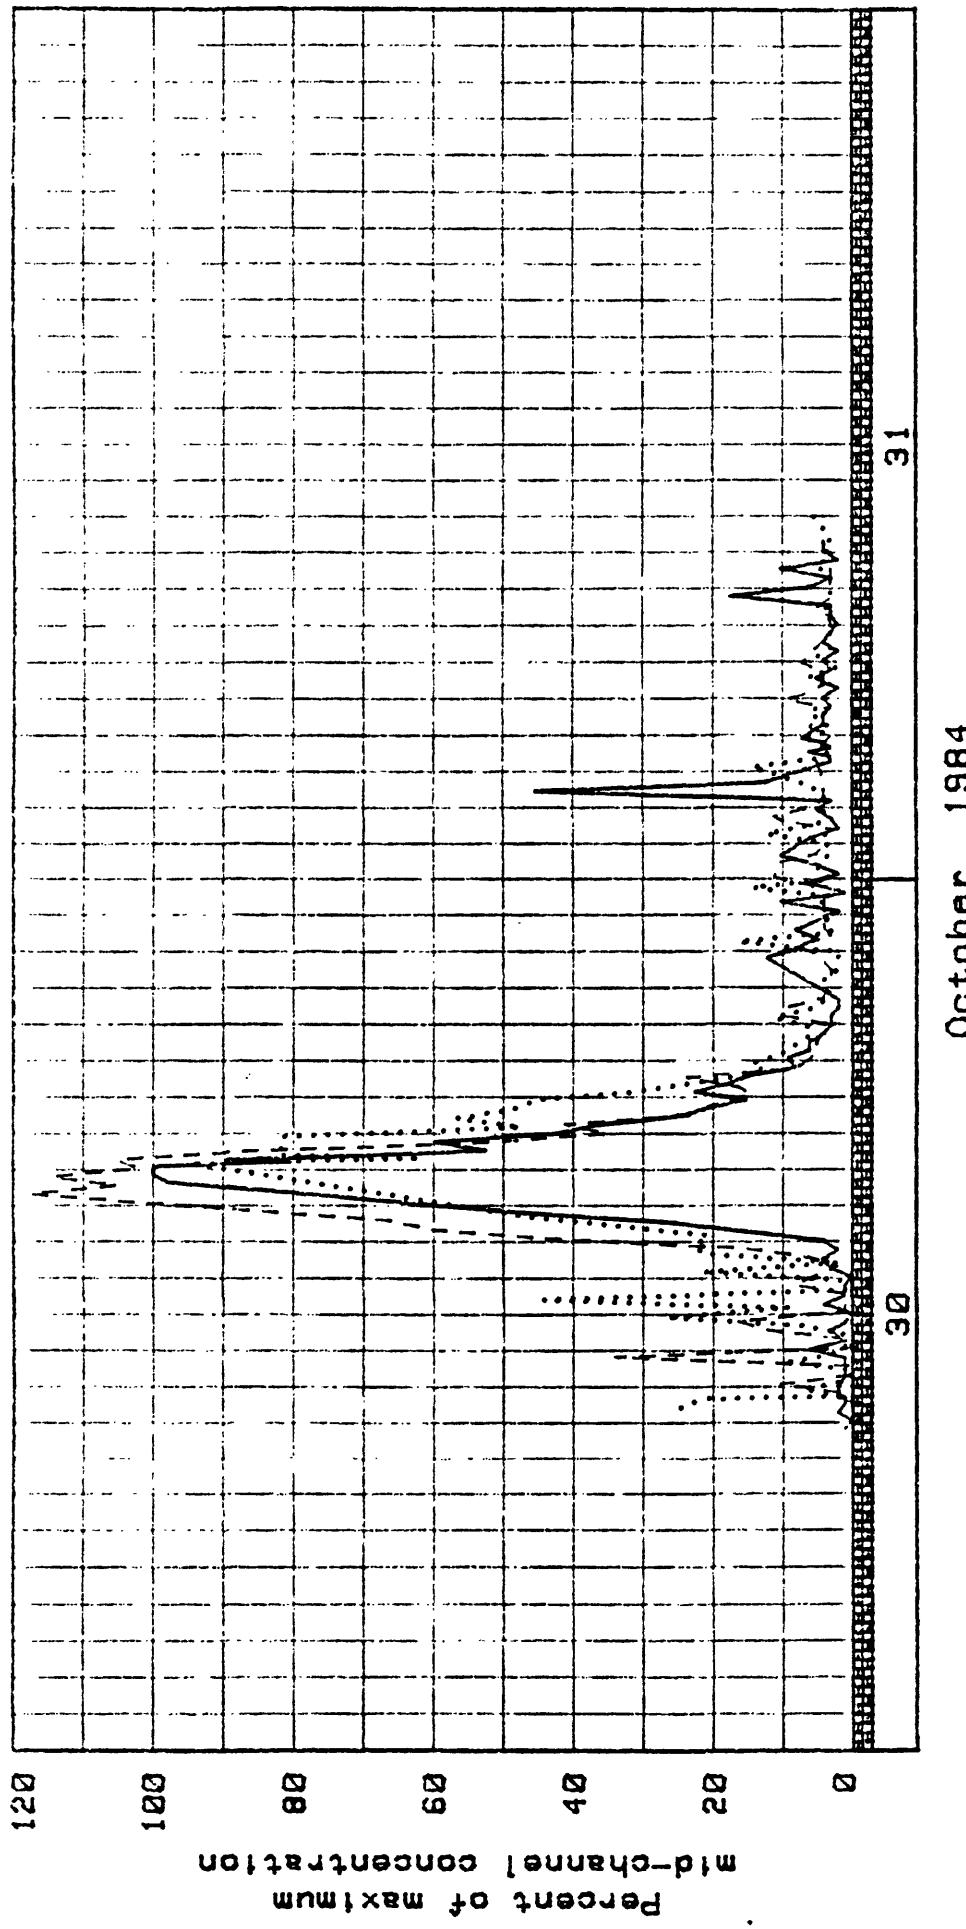

Figure 5. Graph of dye cloud at sampling cross section 43.

Detectable concentrations of the rhodamine WT were first observed at sampling cross section 43, 21.9 miles downstream of Logan Martin dam (at Wilsonville, Alabama) between 0800 and 0930 hours on October 30, 1984. The rhodamine WT cloud appeared to be more dispersed as it passed this cross section than at cross sections 15 and 27. Rhodamine WT concentrations 5 to 10 percent of the maximum concentrations observed at this cross section persisted in the cross section until sampling ceased between 1000 and 1100 hours October 31.

The variability in the rate of movement of the rhodamine WT and the variability in the length of time required for the rhodamine WT cloud to pass individual sampling cross sections in the reach can be attributed to the unsteady nature of flow in the reach. The average rate of movement of the rhodamine WT cloud between these sampling cross sections ranged from 0.15 to 1.36 feet per second and averaged 0.42 foot per second between the injection cross section and sampling cross section 43.

SUMMARY

In order to collect the samples necessary to provide the data for the computation of travel times, dispersion coefficients, and related flow characteristics it was necessary to know the location of the rhodamine WT cloud at all times during the study. Unsteady flow conditions in the study reach made it difficult to predict the rate of movement of the rhodamine WT cloud and consequently its location in the reach. This combination of factors made it necessary to collect and quickly analyze a large number of samples.

The time between sample collection and sample analysis was minimized by automating the sample processing routine as much as was practical. Automatic samplers were used where possible. More than half the samples analyzed were collected with these samplers. The field laboratory was equipped with a microcomputer to minimize the time required to log samples in and to record the results of the sample analyses. Approximately 2,300 samples were analyzed, and the results of the analyses reported and stored in files with a turnaround time averaging less than three minutes per sample.
