ACKNOWLEDGMENTS

This work could not have been accomplished without the assistance and hospitality of numerous property owners in California and Oregon. The authors gratefully acknowledge this debt. The authors are also grateful for chromitite samples contributed by J. P. Albers, J. K. Bohlke, R. C. Evarts, Floyd Gray, G. R. Himmelberg, B. R. Lipin, R. A. Loney, R. J. McLaughlin and Don Walker of the U.S. Geological Survey and by Len Ramp of the Oregon Department of Geology and Mineral Industries, for chemical analyses contributed from the records of W. N. Blair and H. R. Cornwall, and for samples collected in the 1940's by G. L. Bell, F. C. Carter, P. E. Hotz, L. R. Page, and F. W. Wells and which were subsequently retrieved from storage. Field assistance was provided by James B. Barnard.

INTRODUCTION

This report presents platinum group element (PGE) chemical analyses for 323 chromitite samples collected from mines and prospects in California and Oregon (figure 1). Samples collected during this study varied between dunite with disseminated chromite grains to massive chromitite. For purposes of this study samples were defined as chromitite if the chromium content exceeded 10% by weight as measured by six-step semiquantitative emission spectrography (Myers and others, 1961; and Ward and others, 1963). Also presented are the available estimated tonnages and chromium grades which were obtained from published literature (Dow and Thayer, 1946; Wells and others, 1946; Carter, 1948a, 1948b; Ryneerson, 1948, 1953; Wells and Carter, 1950; Carter and others, 1951; Walker and Griggs, 1953; Wells and Hawkes, 1965; and Singer and others, 1981). These data are reported by geologic terranes and regions. The terranes were defined by N.J Page and B.C. Moring (unpub. data, 1985).

DATA

Most samples of chromitite from California were analyzed by fire-assay atomic absorption techniques for palladium, platinum and rhodium and fire assay-spectrographic techniques for iridium and ruthenium. The basic fire-assay technique has been described by Haffty and others (1977) and the fire-assay atomic absorption technique by Simon and others (1978) and Page and others (1980). The spectrographic technique was described by Haffty and others (1980). Detection limits are in part defined by sample size, and under the best conditions the limits are .001, .010, .001, .020, and .100 parts per million (ppm) for palladium, platinum, rhodium, iridium, and ruthenium, respectively.

Most of the samples of chromitite from Oregon were analyzed by comparable techniques described by Cooley and others (1976).

The data were retrieved from the U. S. Geological Survey RASS System (Rock Analysis Storage System) (Van Trump and Miesch, 1977). All PGE values are reported in parts per million. The data are presented in table 1.

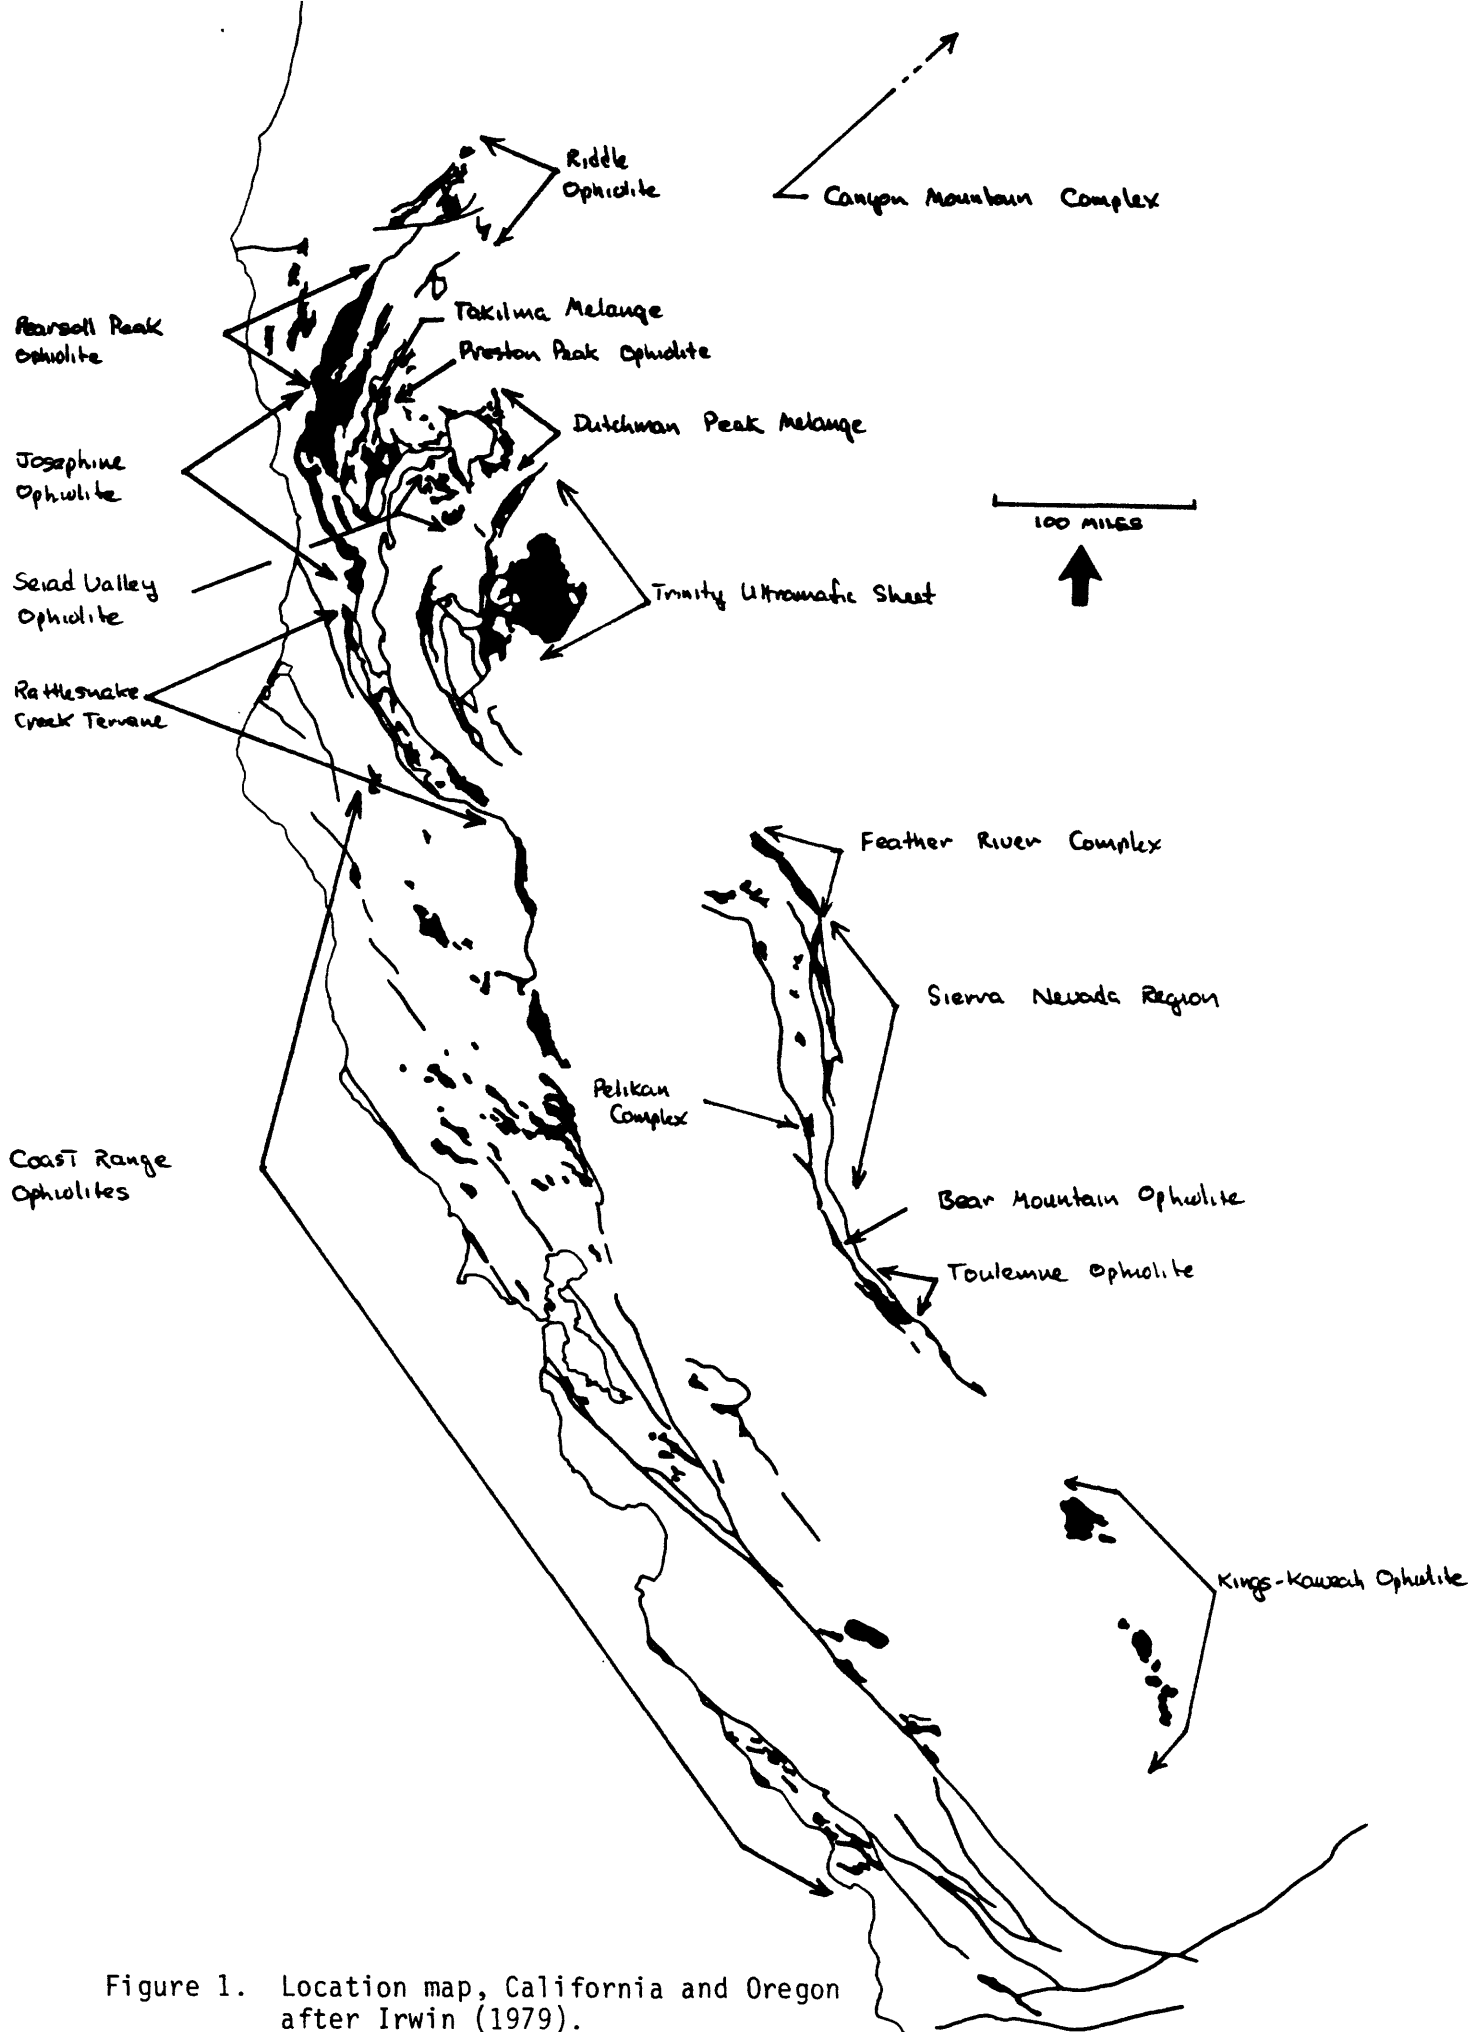

Figure 1. Location map, California and Oregon after Irwin (1979).

Table 1.--Geochemical analyses

[The location of each chromitite occurrence is given in Universal Transverse Mercator (UTM) eastings and northings. The values for the platinum group elements are given in parts per million. A less than symbol (<) indicates that the element is detectable and less than the value indicated. Trace (Tr) indicates that the element is present but below the routine limit of determination and too low to assign a value. Not detected (N) indicates that the line for this element was not seen on the spectrogram. Blank (B) indicates that this sample was not analysed for this element. Analysts: L. Bradley; J. Cornell; C. Gent; W. Goss; H. Groeneboer; J. Haffty; A. Haubert; A. Love; J. McDade; R. Moore; L. Riley; and S. Wilson.]
