ABSTRACT

Ice velocity data are presented for the lower reach of Columbia Glacier, Alaska. The data span a 29 day period and contains 1,072 angle sightings from two survey stations to 22 markers placed on the ice surface, and 1,621 laser measurements of the distance to one of those markers (number 11) from another station. These short-interval observations were made to investigate the dynamics of the glacier and to provide input to models for estimation of future retreat and iceberg discharge. The mean ice velocity (at marker number 11) was approximately 9 meters per day and ranged from 8 to >15 meters per day. The data set includes a well defined 2-day 50-percent velocity increase and a clear pattern of velocity fluctuations of about 5 percent with approximately diurnal and semi-diurnal periods.

INTRODUCTION

Columbia Glacier is a large, grounded, iceberg-calving glacier located in south-central Alaska about 38 km (kilometers) west of Valdez (fig. 1). It has an area of approximately 1100 km^2 (square kilometers) and extends 65 km along its main branch to the terminus in Columbia Bay. A short distance in front of the terminus lies a moraine shoal with a maximum depth of about 23 m (meters) below mean sea level. Much of the ice in the lower reach of the glacier lies below sea level. Although the glacier thickness is generally sufficient to overcome the buoyant effect of the water, a notable exception may have occurred briefly during the summer of 1984, when a localized region near the terminus appeared to be floating.

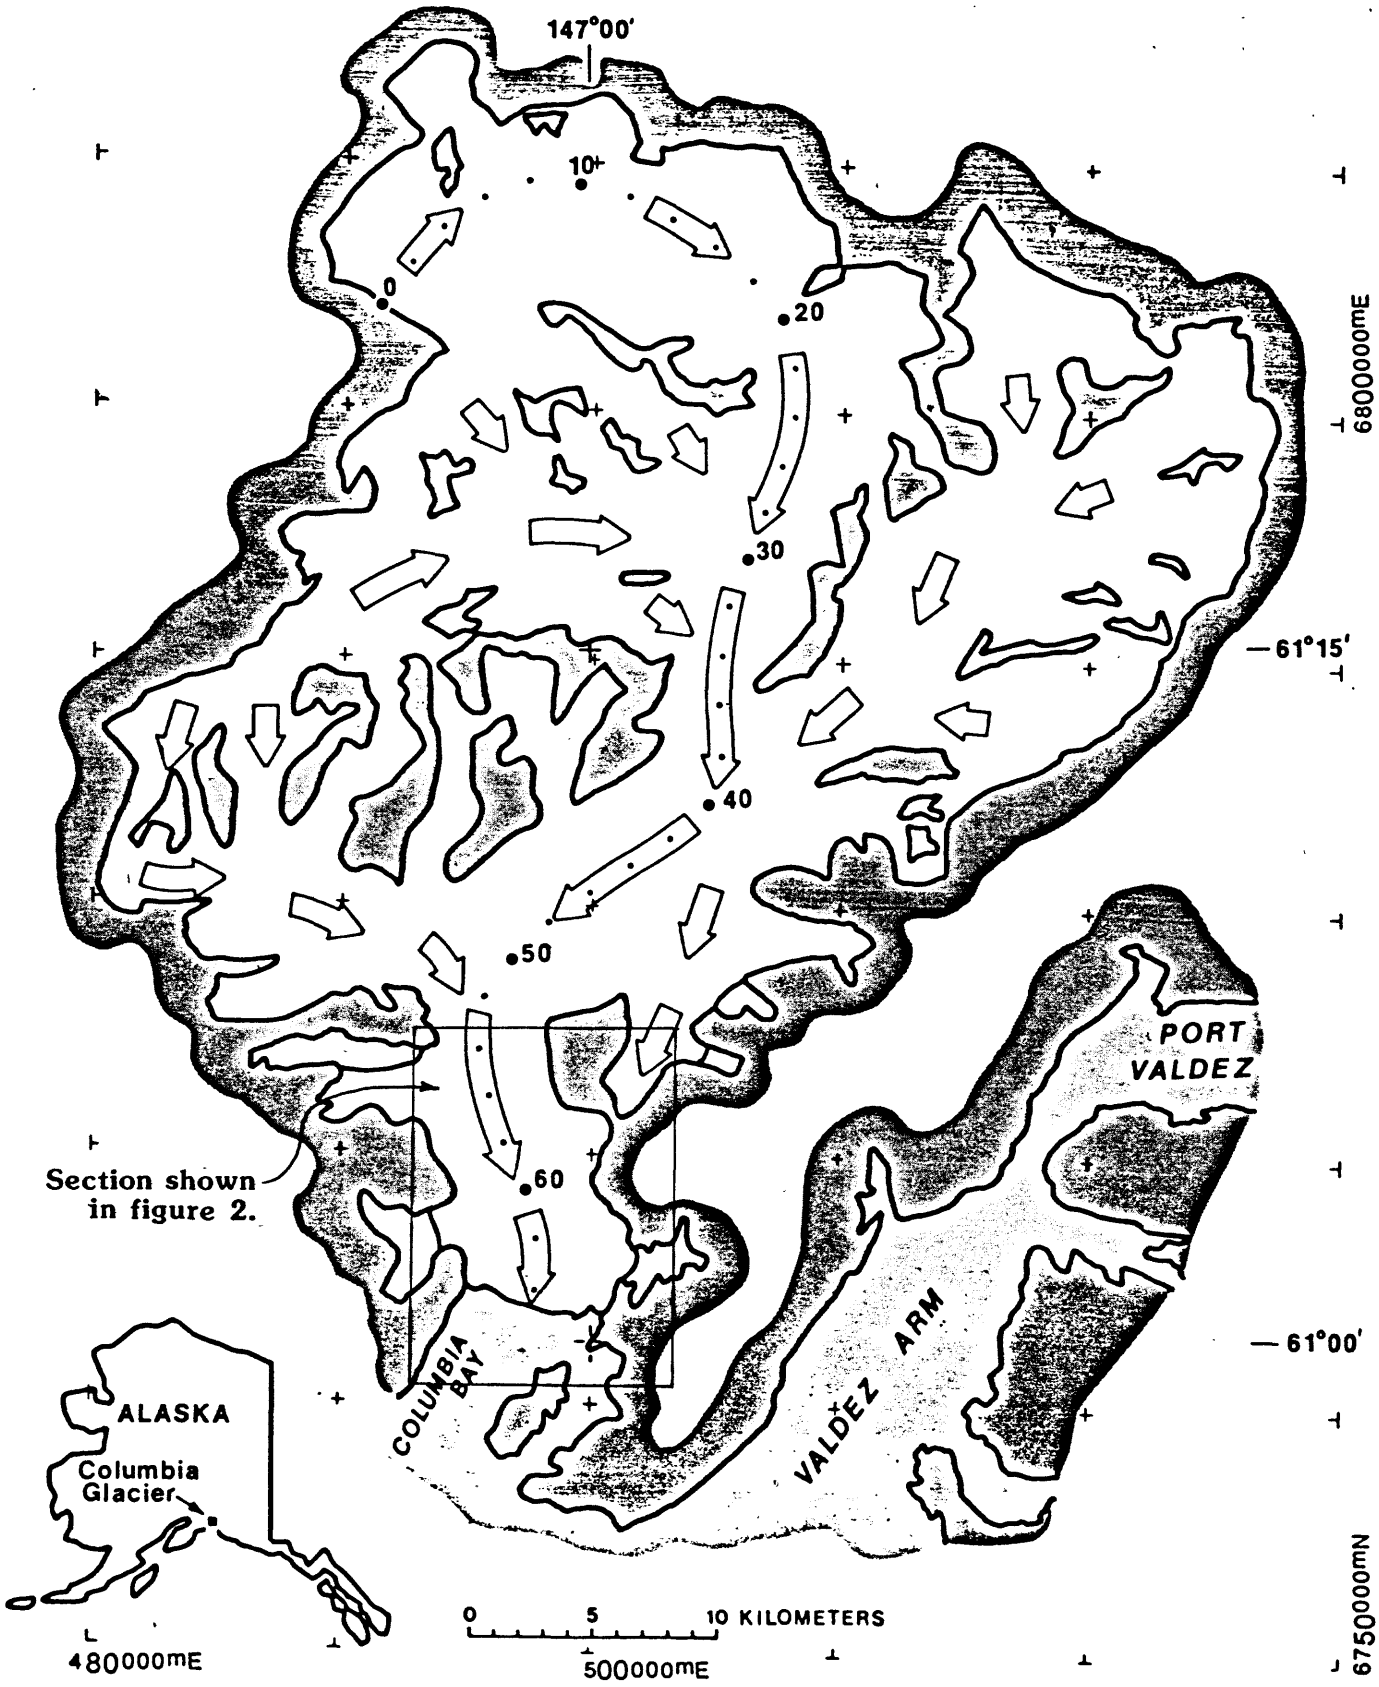

Figure 1.--Index map of Columbia Glacier, Alaska. Arrows show general direction of flow. Main ice stream is indicated by longer arrows and dots at 2-kilometer intervals along the curvilinear, longitudinal coordinate system.

In 1974 Austin Post surmised that an irreversible drastic retreat would ensue should the glacier retreat slightly behind the moraine shoal (Post, 1975). A major research program on Columbia Glacier (Meier and others, 1978) was begun in 1974. Since 1978 the terminus has retreated from the crest of the shoal into water more than 200 m deep. A few kilometers behind the terminus the water is more than 350 m deep.

During the transition from a stable state to one of retreat, knowledge of both the calving flux and the ice velocity is important to understanding the dynamics of the glacier, as well as the continued estimation of iceberg discharge. Two empirical calving relations were developed (Brown and others, 1982; Sikonia, 1982) and then used in numerical models in order to assess the future behavior of Columbia Glacier (Rasmussen and Meier, 1982; Sikonia, 1982; Bindschadler and Rasmussen, 1983). The numerical results indicated that the lower reach would begin disintegrating during the 1980's and that the calving flux would sharply increase. The model results appear to be valid, as the predicted retreat and flux increase (Meier and others, 1980) are occurring. The terminus has retreated about 2 kilometers between 1978 and 1984, and the calving flux approximately tripled between 1978 and late 1984 (Meier and others, 1985). However, the models were very sensitive to the assumed calving relation and therefore may not be applicable in future interpretations.

The terminus configuration and the rate of calving have changed since the early 1980's, which suggests that the calving relations derived empirically from data pertaining to an earlier configuration and mode may no longer be appropriate. The model results are highly sensitive to the calving relation because that relation uses the glacier terminus as a boundary condition. The empirical calving relations were hypothesized first, then calibrated from a data set that included only a few variables, that was relatively sparse in space and time, that was subjected to only preliminary data reduction techniques, and that pertained to

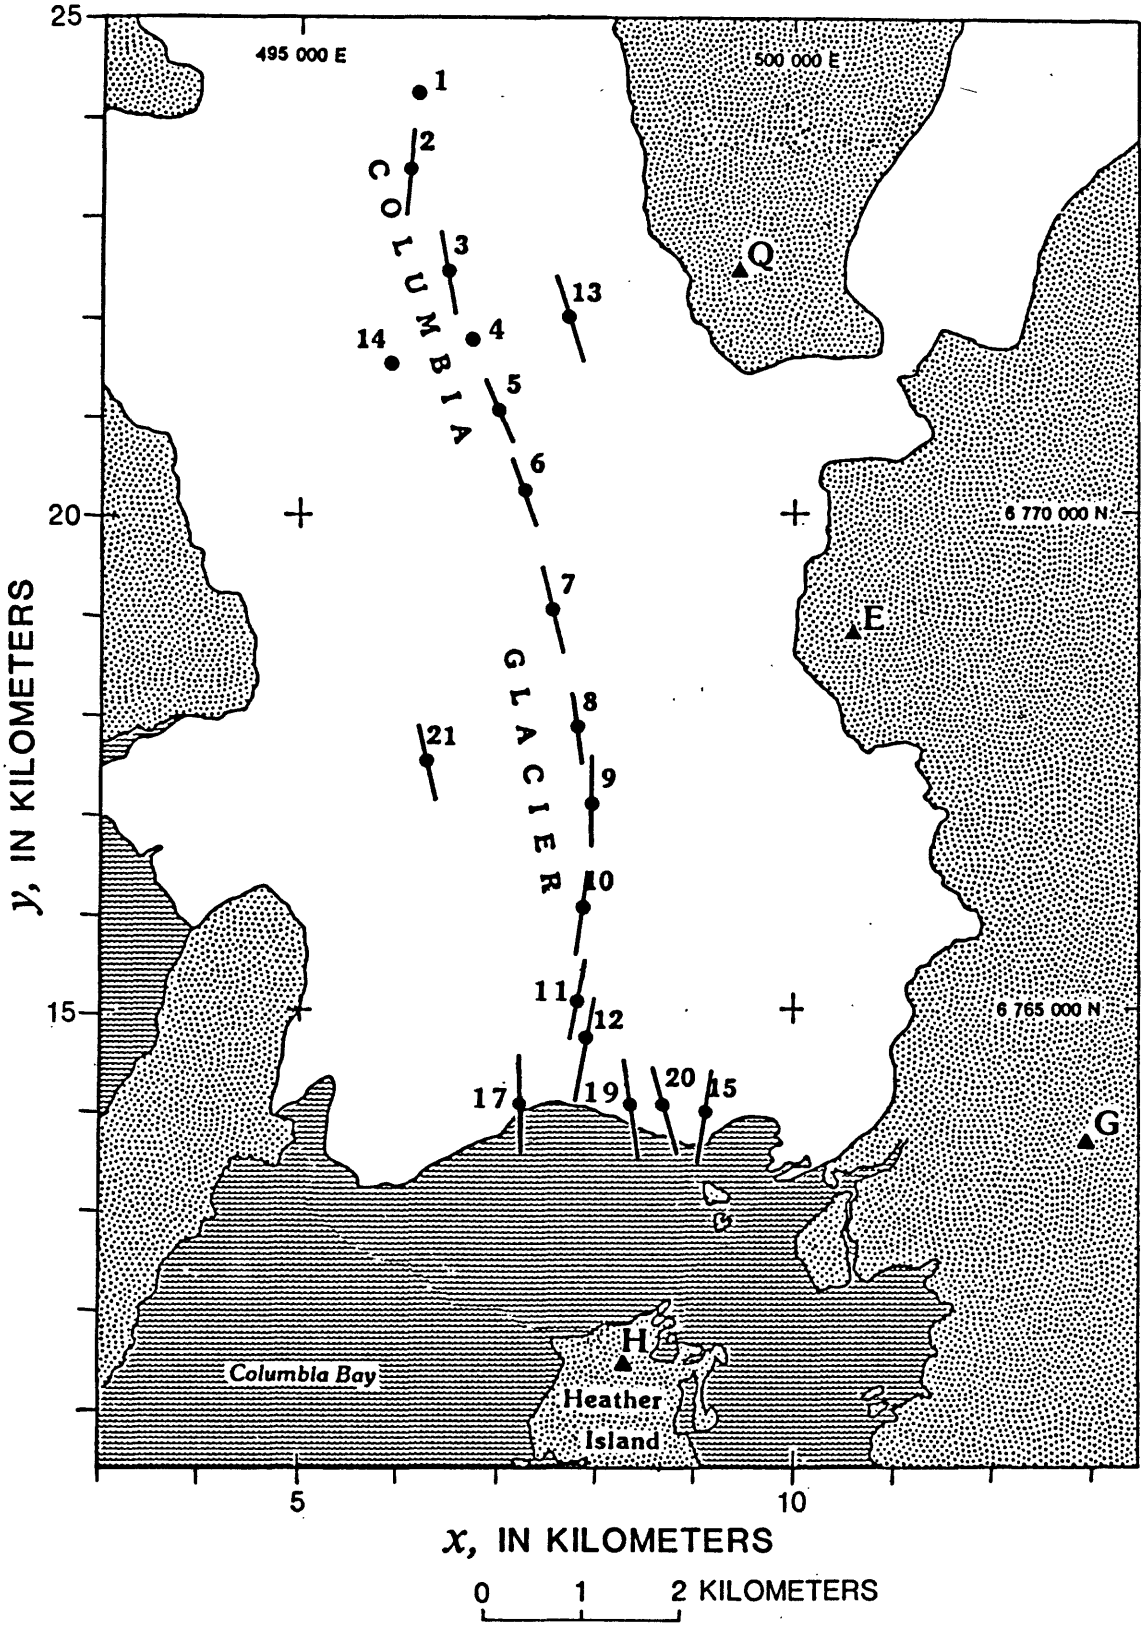

Figure 2.--Survey stations and approximate August 13, 1984 marker positions (dots). Line segments indicate mean direction of flow, and lengths have no significance. Sightings of the markers were made from New Gilbert (G) and New Quickie (Q), using Easy (E) as the azimuth reference, and the distance to marker 11 was measured from the EDM-site (H). The meteorological data used to correct the EDM results were obtained at station (M). The terminus position is that of August 15, 1985.

an earlier configuration of the glacier and mode.

Observations by Austin Post (written communication, 1984) during the summer and fall of 1983 suggested the association of high calving rates with periods of heavy rainfall although this was not true during the 1984 field experiment. Detailed studies of Variegated Glacier (Kamb and others, 1985) indicated that rapid sliding of a glacier during a surge was controlled by water at the bed as were "minisurges" propagating downglacier before and during a surge. Obviously the connection between ice flow, water at the bed, and iceberg calving needs to be investigated.

To that end, an intensive field program in August-September 1984 collected data on calving, ice velocity, terminus position, seismic activity, meltwater production and rainfall, other meteorological variables, tide stage, and runoff from marginal rivers. This data set, when used in conjunction with other data collected systematically but less frequently since about 1977, will be useful in many investigations: those mentioned in this report, others identified but not mentioned, and others that have not been identified yet. The ice-velocity data in this report include both the comprehensive listing of 1,072 survey sightings from two survey stations used to sight 22 markers placed on the ice surface and the comprehensive listing of 1,621 laser measurements of the distance to one of those markers (no. 11) from another station. This report also describes the data-reduction methods and a few preliminary results.

THE 1984 VELOCITY MEASUREMENT FIELD PROGRAM

As a part of the multidisciplinary 1984 field program, the velocity data were obtained in the following manner. Survey stations New Gilbert and New Quickie were occupied 29 and 20 days respectively, beginning August 7 (Julian day 220) during which daily or more frequent sightings of many of the 22 surface marker positions were recorded (fig. 2). The markers were 1-meter tetrahedra constructed from tubular steel covered with fluorescent orange cloth and weighted

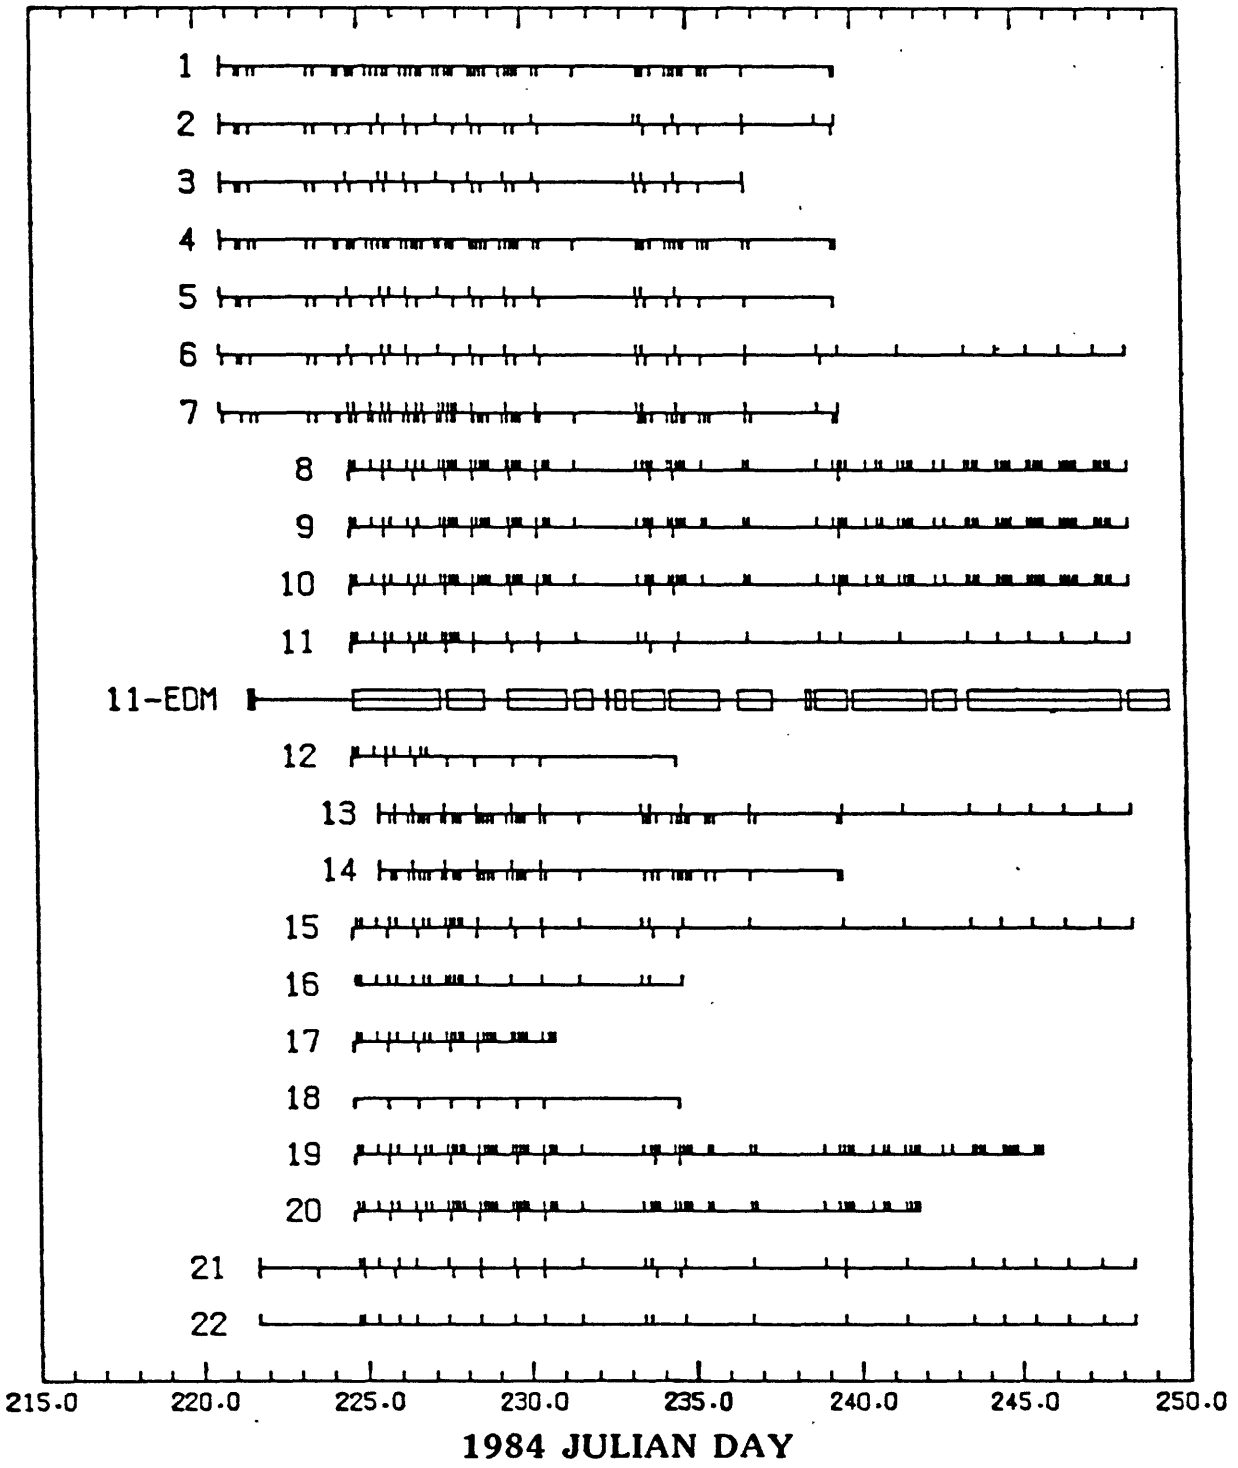

Figure 3.--Period of record of sightings (markers 1-22) and distance measurement (marker 11). For each marker, the upward-pointing tick indicates an azimuth sighting from New Gilbert (G), a downward-pointing tick, one from New Quickie (Q). For marker 11, the rectangles indicate periods during which a distance measurement was made at least every three hours.

with rocks. These were placed by helicopter atop ice pinnacles within predetermined areas on the lower 11 km of the glacier. All markers visible from each station were surveyed once a day, and markers closer to each respective station were surveyed every 3 to 5 hours during daylight hours (fig. 3). Some breaks in the data occurred during periods of fog or heavy rain when the markers could not be seen.

On August 8 distance readings began with a recording electronic distance meter (EDM) located atop a bluff on the north end of Heather Island (fig. 2). The target was a three-prism reflector assembly fixed to two vertical stakes to minimize rotation and wind vibration. The stakes were drilled into the ice about 3.8 km from the EDM, or about 1 km upglacier from the terminus. Readings were taken at 15-minute intervals day and night. In the first several days there were a few short recording gaps during equipment failures. After this shakedown period, the major gaps were caused by fog or heavy rain.

The Hewlett-Packard 3808 EDM[1] uses a gallium arsenide lasing diode with a non-visible beam divergence of 0.0370 grads and a factory rated accuracy of 5mm (millimeter) + 1mm/km, or 9 mm at the beginning target distance of 3.8 km (Adams, 1978). The maximum rated range is 10 km but may require as many as six reflectors. These specifications are accurate during minimal heat shimmer. The details of the data reduction and atmospheric correction are discussed in subsequent sections.

The HP-3808 was operated in a remote function mode, and was triggered electronically by interval timers. Digital output of the metric distance measurements in binary coded decimal was converted by a Wild Heerbrugg interface into signals compatible with an HP-41 series calculator. The data from this interface were automatically transmitted to a HP-41cv calculator, thermal printer, and a digital cassette drive. All systems were operated on external 6 or 12 volt lead-acid

[1] The use of brand names in this report is for identification purposes only and does not imply endorsement by the U.S. Geological Survey.

batteries, which were maintained by a 132 watt array of solar cells fixed to the roof of the instrument shelter. A 3 kilowatt generator was used intermittently during extended periods of foul weather. This system represents a unique field application of data acquisition equipment normally intended for office use.

In operation, the distance reading was automatically stored in the memory of the HP-41 with a time and date, and printed out on thermal paper tape which provided a vital permanent record, immune to power fluctuations and memory loss. The EDM required re-aiming 2 or 3 times a day because the target was not moving directly toward the instrument. Small data gaps appear when this was not done regularly (fig. 3).

Suggested improvements to these instruments include illuminated cross-hairs in the telescope of the instrument for nighttime target viewing with the aid of a flashlight to illuminate the target reflector. This would allow re-aiming during the night as well as switching between multiple targets at any time of day.

DATA REDUCTION

Survey Markers

A local coordinate system with x positive to the east and y positive to the north is related to the Universal Transverse Mercator system according to

$$\begin{pmatrix} x \\ y \end{pmatrix} = \frac{1}{0.9996} \begin{pmatrix} E_{UTM} - 490{,}000 \text{ m} \\ N_{UTM} - 6{,}750{,}000 \text{ m} \end{pmatrix} \quad (1)$$

and z is the vertical coordinate, positive upward. Time is represented by the Julian day of 1984; it is 214.000 at 0000 hours local time on August 1, 1984 and increases by 1 each day thereafter.

The EDM instrument (H) was on Heather Island and Kern DKM2-AE theodolites were operated at stations New Gilbert (G) and New Quickie (Q), where azimuth angles $\hat{\theta}_G$ and $\hat{\theta}_Q$ to the markers were measured in grads to the right of station Easy (E). These stations are shown in figure 2 and their coordinates are given in

Table 1.--Survey stations.

[Coordinates x, y, z are in local coordinate system (equation 1) in meters].

Station	x	y	z
Easy (E)	10,543.3	18,808.9	461.1
New Gilbert (G)	12,923.2	13,643.6	448.4
New Quickie (Q)	9,441.6	22,464.6	701.8
EDM-site (H)	8,272.3	11,373.6	26

table 1. These letters will be used as subscripts as well as subscript T meaning Target.

The original angles $\hat{\theta}_G$ and $\hat{\theta}_Q$ are transformed to radians measured in the mathematically positive direction from the positive x-axis according to

$$\begin{pmatrix} \theta_G \\ \theta_Q \end{pmatrix} = \begin{pmatrix} 8.285744 \\ 5.005084 \end{pmatrix} - \frac{\pi}{200} \begin{pmatrix} \hat{\theta}_G \\ \hat{\theta}_Q \end{pmatrix} \tag{2}$$

in which the constants are related to the azimuths to station Easy from stations New Gilbert and New Quickie.

Neglecting the effect of Earth's curvature in determining horizontal coordinates, the equations of the two sighting lines are:

$$y = \begin{pmatrix} a_G \\ a_Q \end{pmatrix} x + \begin{pmatrix} b_G \\ b_Q \end{pmatrix} \tag{3}$$

Letting s represent either G or Q, the slope in the x,y plane is $a_S = \tan \theta_S$ and the intercept is $b_S = y_S - a_S x_S$ (fig. 4). The coordinates of their intersection are

$$\begin{pmatrix} x_T \\ y_T \end{pmatrix} = \frac{1}{a_Q - a_G} \begin{pmatrix} b_G - b_Q \\ a_Q b_G - a_G b_Q \end{pmatrix} \tag{4}$$

in which the subscript T denotes the survey target.

Taking into account the effects of both refraction and Earth's curvature, by means of the factor (Bouchard and Moffitt, 1972) $c \approx 6.8 \times 10^{-8}$ for distances in meters, the vertical coordinate of the marker is given by

$$z_T(s) = z_S + h_S + (cr_S - \tan \phi_S)\, r_S \tag{5}$$

in which h_S is the height of the instrument above the ground, Z_S is altitude of station, ϕ_S is the elevation angle in radians as measured below the local horizontal, and $r_S = [(x_S - x_T)^2 + (y_S - y_T)^2]^{1/2}$. As the vertical coordinate can be estimated from either station independently from observations at the other station, a linear combination of the two estimates may be used for the altitude of the marker.

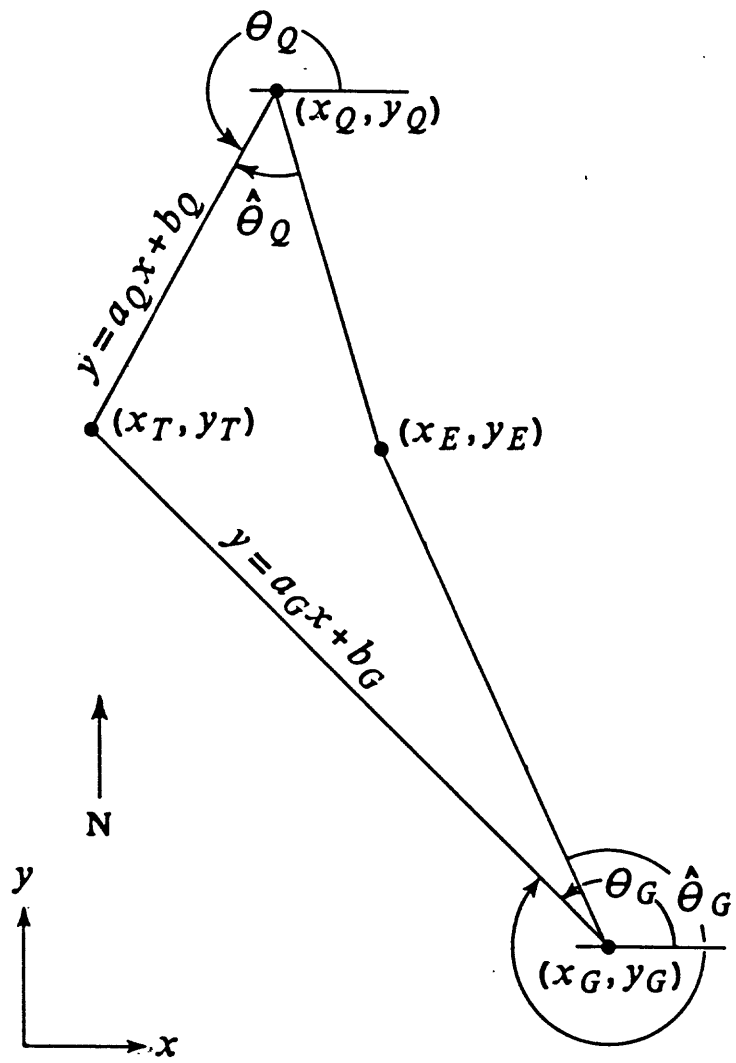

Figure 4.--Horizontal triangulation from survey stations New Gilbert (G) and New Quickie (Q), using Easy (E) as the reference.

$$z_T = \lambda z(G) + (1-\lambda)z(Q) \qquad (6)$$

Determining the optimum value of λ (L. A. Rasmussen, U.S. Geological Survey, written communication, 1985) is beyond the scope of this report.

Because sightings of the moving markers were not made simultaneously from the two survey stations, time interpolation in the angle data--from one, or the other, or sometimes both stations--was used to get synchronous values for use in equations 2-6. The period of record of observation of each of the markers is shown in figure 3. Marker trajectories over this short period of record are very nearly straight lines; trajectory directions and representative marker positions are given in table 2.

Quality codes--based on comparison of forward and reverse sightings and, for the azimuth angles, on the apparent change of azimuth to the reference station Easy between the beginning and the end of a set of sightings--were assigned to each of the measured angles, indicating the probable error: 0 for 0.0030 grads, 1 for 0.0060, 2 for 0.0090, and 3 for 0.0120. Reference elevation angles to a fixed, known point were not regularly made, as a check on atmospheric refraction; therefore, this report does not include c-values for use in equation 5. The individual angles, along with the times of the sightings and the quality codes, are given in Appendix 1.

Each of two points (x_1, y_1) and (x_2, y_2) on a marker's trajectory--which is taken to be a straight line--is determined by applying equation 4 to a pair of azimuth angles, one from each of the two survey stations, generally with the use of some time interpolation to make them synchronous. The position of the marker corresponding to azimuth θ_S from survey station (x_S, y_S) is

$$\begin{pmatrix} x \\ y \end{pmatrix} = \begin{pmatrix} x_S \\ y_S \end{pmatrix} + \frac{a}{b} \begin{pmatrix} 1 \\ \tan \theta_S \end{pmatrix} \qquad (7)$$

in which $a = (x_1 - x_S)\,\Delta y - (y_1 - y_S)\,\Delta x$ and $b = \Delta y - \Delta x \tan \theta_S$, with $\Delta x = x_2 - x_1$ and $\Delta y = y_2 - y_1$. Given the time rate of change $\dot{\theta}_S$ of the azimuth angle as

Table 2.--Marker positions and trajectory inclinations. The positions are for t = 226.000 (0000 hours local time on August 13, 1984), except that t = 220.837 for no. 1 and t = 220.806 for no. 4. [Coordinates x, y, z are in local coordinate system (equation 1) in meters].

Marker	x	y	$\Delta\xi/\Delta\psi$
1	6147	24274

21	6256	17509	-0.231

well, the velocity of the marker along the trajectory is

$$\begin{pmatrix} u \\ v \end{pmatrix} = \frac{(1 + \tan^2\theta_s)\, a\, \dot{\theta}_s}{b^2} \begin{pmatrix} \Delta x \\ \Delta y \end{pmatrix} \tag{8}$$

in which u is the component in the x-direction, and v is the component in the y-direction.

EDM Measurements

The EDM readings were recorded digitally at approximately 15-minute intervals except during periods of equipment failure or impaired visibility (fig. 3). They were adjusted for variations of atmospheric density (Adams, 1978) where the adjusted value r is given by

$$r = \left(279.42 - \frac{105.885\ p}{273.2 + \overline{T}}\right) \times 10^{-6}\ \hat{r} \tag{9}$$

in which p is the pressure in mm of mercury, $\overline{T}$ is the air temperature in degrees Celsius, and r is the original distance reading. The values of $\hat{t}$, r, and $\hat{r}$ are given in Appendix 2. The adjustment was small ($-41 \leq r - \hat{r} \leq 1$ mm) especially compared with the average daily change in r, which was about 9 m. The p and $\overline{T}$ data were taken at a site approximately 300 m to the northwest of the EDM instrument site at an altitude of 15 m above sea level and 1 m above the ground (Fig. 2).

Given two points (x_1, y_1) and (x_2, y_2) on the trajectory of the EDM-reflector (marker 11)--which is assumed to be a straight line--and given the distance r from the EDM-instrument at (x_H, y_H), the point on the trajectory is given by

$$y = y_H + (mF + \sqrt{Mr^2 - F^2}\,)/M \tag{10}$$

$$x = my - f$$

in which $M = m^2 + 1$ and $F = f + x_H - my_H$, with $m = (x_2 - x_1) / (y_2 - y_1)$ and $f = (x_2y_1 - x_1y_2) / (y_2 - y_1)$. Given the time rate of change $\dot{r}$ of the distance as well, the velocity of the reflector is given by

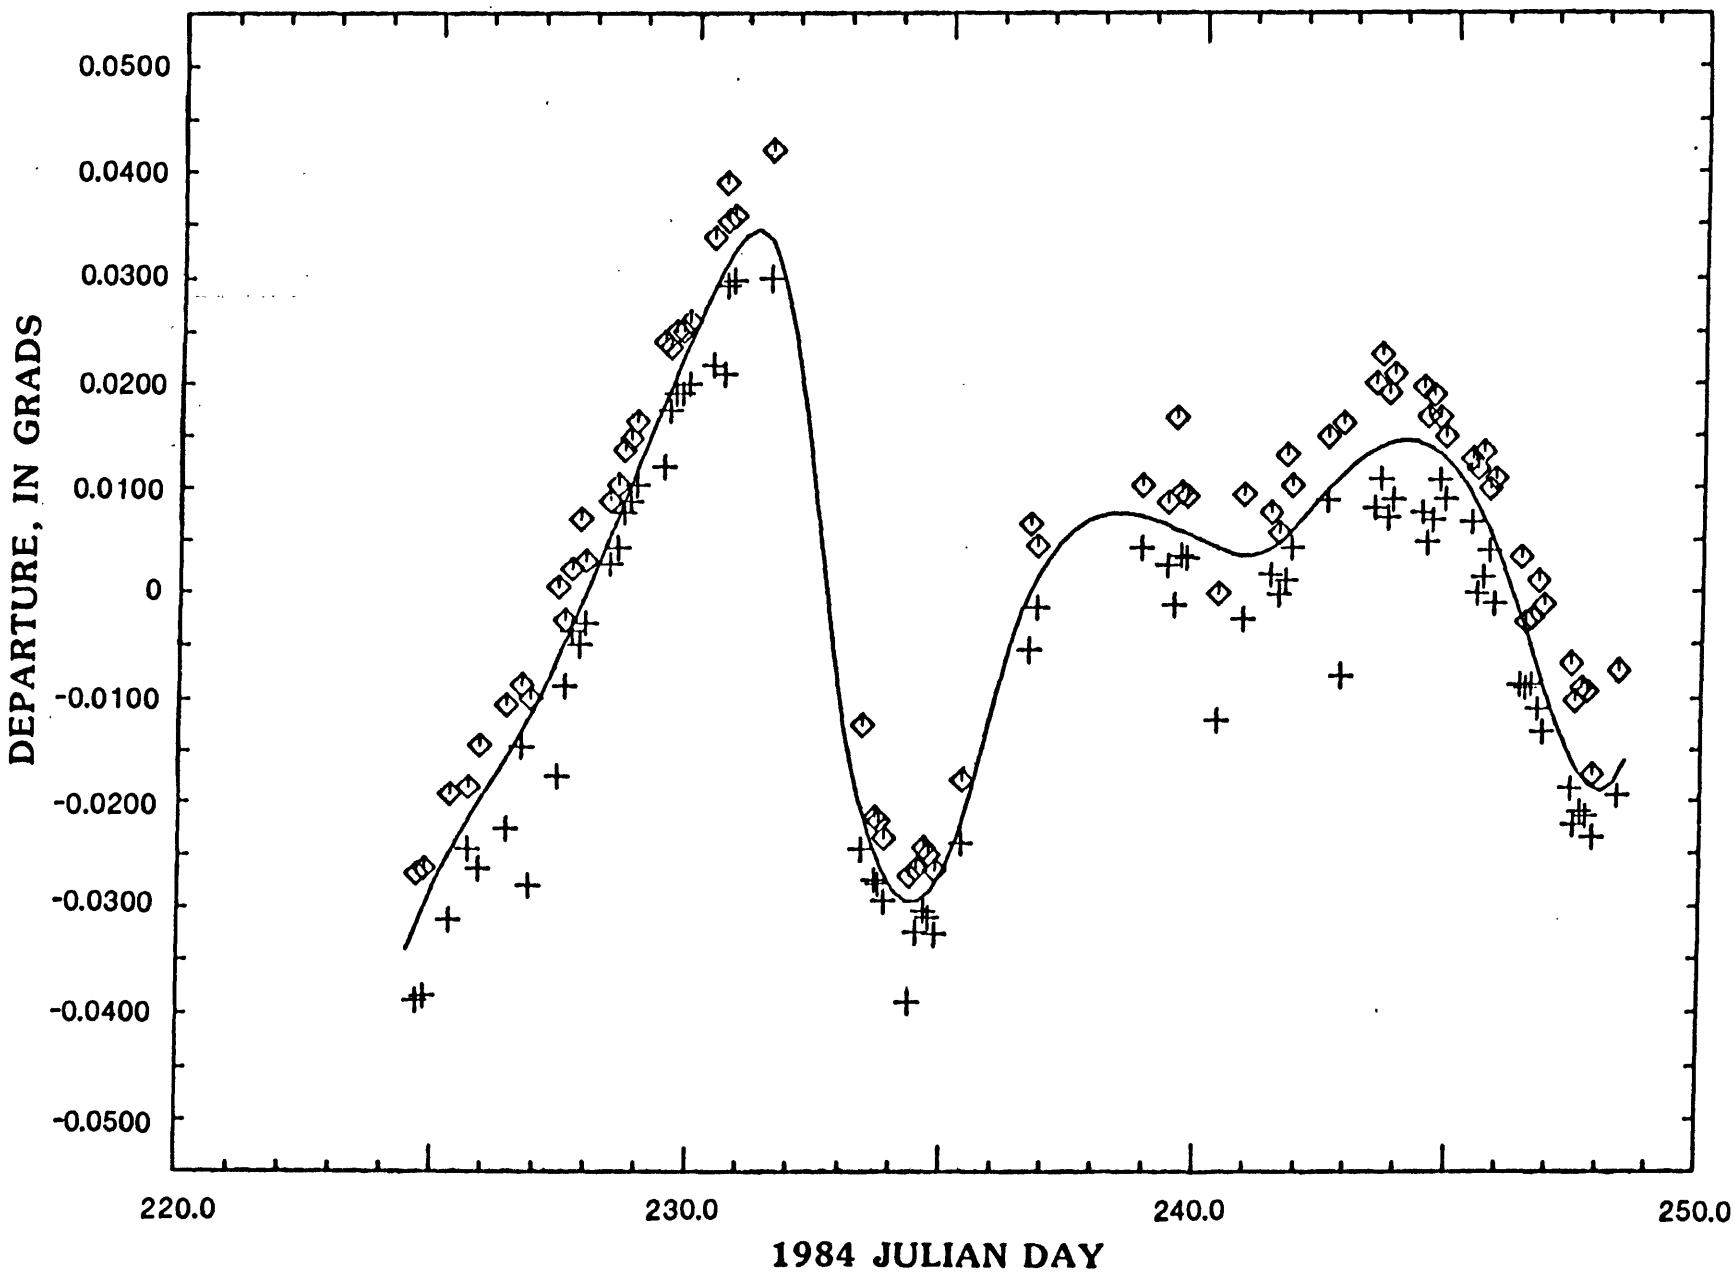

Figure 5.--Departure of azimuth angles from the long-term trend, for marker 10 as surveyed from New Gilbert (G). The ordinates $\Delta\theta + \varepsilon$ (squares) and $\Delta\theta - \varepsilon$ (crosses) are taken to be the error bar for each sighting, where $\Delta\theta$ is the departure and ε is the error associated with the sighting. Shown also is a smooth curve fit by hand to the error bars.

$$\begin{pmatrix} u \\ v \end{pmatrix} = \frac{r\dot{r}}{\sqrt{Mr^2-F^2}} \begin{pmatrix} m \\ 1 \end{pmatrix} \tag{11}$$

The foregoing involves, essentially, the intersection of a circle with a straight line, the general solution for which has been particularized here--with respect to the sign taken with the radical and the expression of the slope--for the trajectory-instrument configuration at Columbia Glacier.

VELOCITY DETERMINATION

When azimuth angles to a marker were available from both survey stations, they were used (equations 3,4) to establish the marker's x, y trajectory, which was approximated by a straight line (table 2). The azimuth angles θ from the station with the more numerous sightings of a marker were then used (equation 8) to estimate the velocity along the trajectory. To get the derivative $\dot{\theta}$ and to get velocity as a function of time, it is necessary to have θ as a function of time.

A single least-squares cubic polynomial P(t) was used to represent the long-term (period of record) trend of the θ vs t data, and the departures $\Delta\theta$ from the cubic of the individual θ-values were then considered as a function of t. Where ε is the error implied by the quality codes assigned to the individual sightings, an error bar was formed by plotting (fig. 5) $\Delta\theta + \varepsilon$ and $\Delta\theta - \varepsilon$ at the t-coordinate of each θ-value. A smooth curve f(t) was fit by hand to the error bars, $\theta(t) = P(t) + f(t)$ and $\dot{\theta}(t) = \dot{P}(t) + \dot{f}(t)$ being used to estimate the quantities in equation 8. The two velocity components are combined to give the total speed $\sqrt{u^2 + v^2}$ along the trajectory as a function of t in figure 6.

A cubic spline (Reinsch, 1967) was used to smooth the n = 1,621 distance values r_i obtained from the EDM. The spline g(t) consists of a separate cubic polynomial on each interval (t_i, t_{i+1}), has continuity of function value and first two derivatives, and minimizes

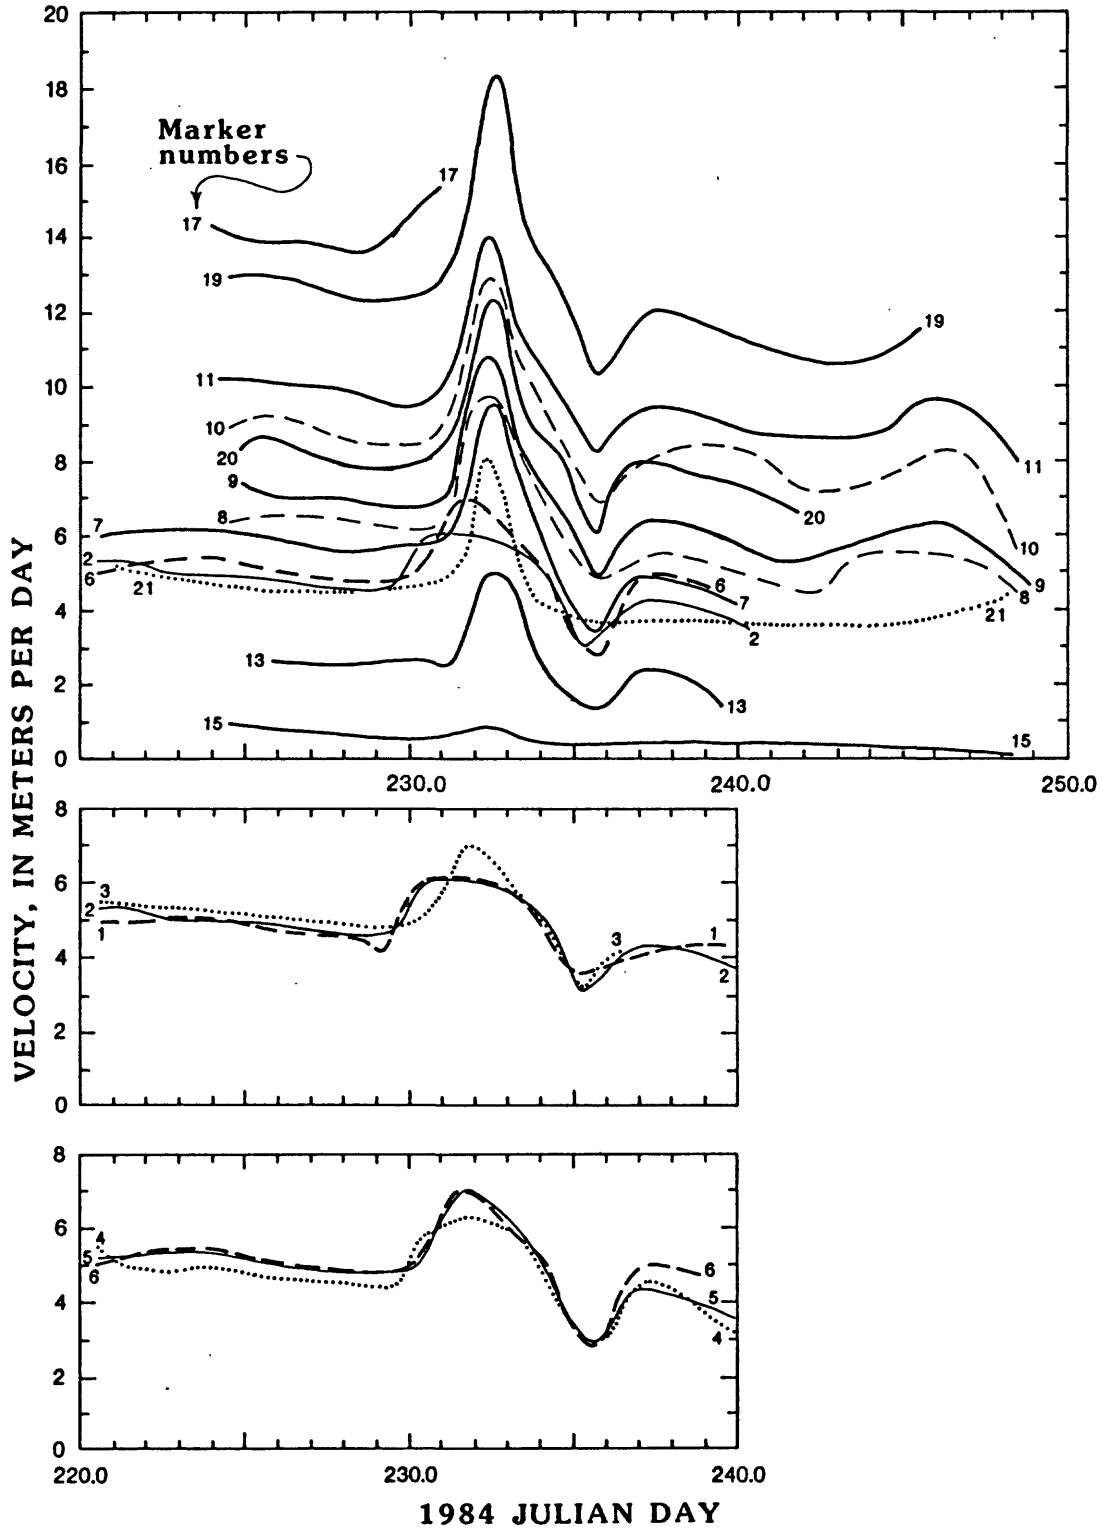

Figure 6.--Velocity of markers along their trajectories. Markers 1 through 3 and 4 through 6 are shown separately for clarity. Omitted from this analysis were marker 12, for which frequent sightings were lacking from both survey stations; marker 14, which apparently fell from the serac on which it was placed; and markers 16, 18, and 22, which were each sighted from only one survey station.

$$I = \int_{t_1}^{t_n} [\ddot{g}(t)]^2 \, dt \tag{12}$$

subject to

$$\frac{1}{n} \sum_{i=1}^{n} [g(t_i) - r_i]^2 \leq \sigma^2 \tag{13}$$

Where σ = 10 mm includes the standard error of the instrument--5 mm plus 1 mm for each km of distance (Adams, 1978), and 1 mm error due to recording the time to the nearest minute.

The function value of the spline and its first derivative $\dot{g}(t)$ are used as estimates of the quantities r and $\dot{r}$ in equations 10 and 11. The two velocity components are combined to give the total speed along the trajectory as a function of t in figure 7, which also shows the curve for marker 11 determined from the Survey sightings (fig. 6). The agreement between the two curves is good except near the ends of the interval because the interpolation of $\Delta\theta$ (fig. 5) is less reliable at the ends.

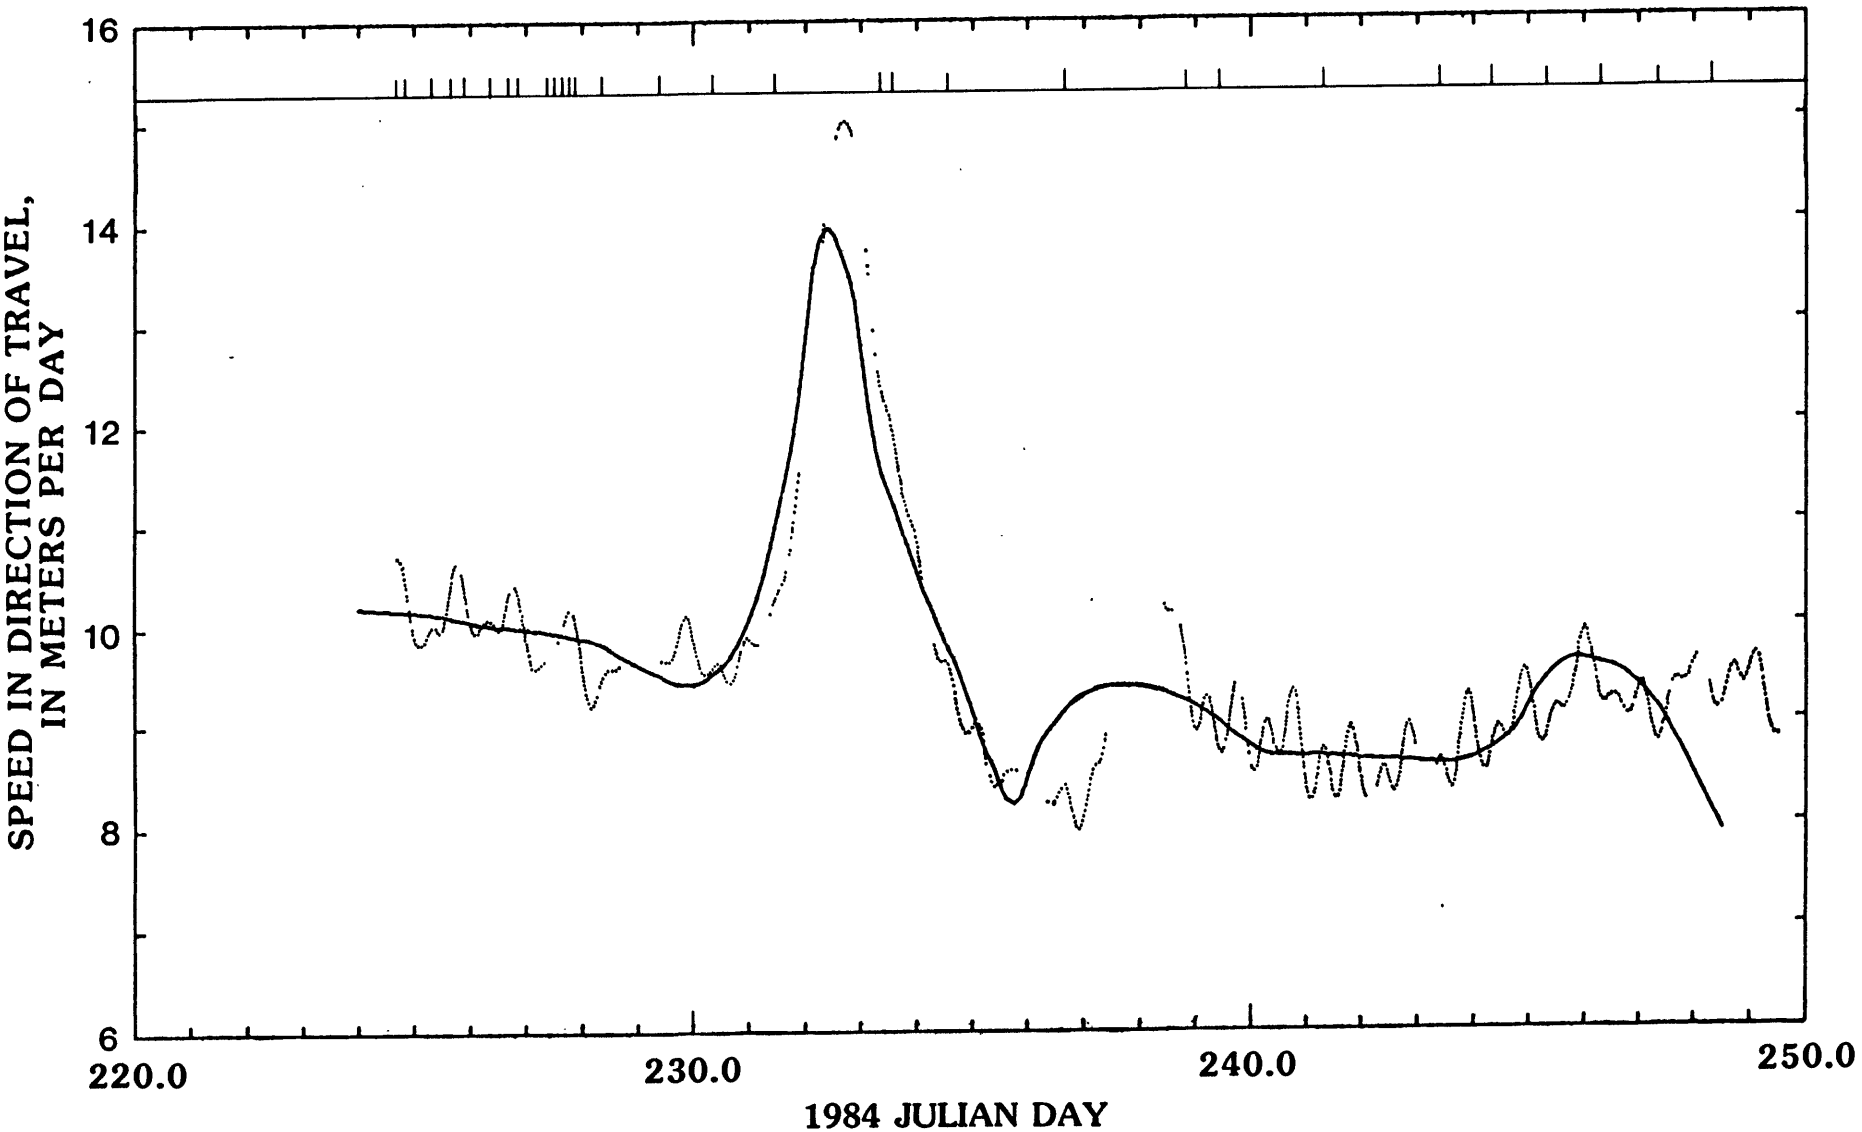

Figure 7.--Velocity of marker 11 along its trajectory determined by two methods. The velocity (solid) determined by equation 8 from azimuth angles sighted at New Gilbert is shown for comparison with the velocity (dotted) determined by equation 11 from the distance measurements made at the EDM-site. Rake scale at top shows period of record for survey sightings to the marker (fig. 3).

Appendix 1. Sightings of markers from survey stations.

The time shown $\hat{t}$ is 200 less than the 1984 Julian Day, which is 214.000 at 0000 hours on August 1, 1984 and increases by 1 each day thereafter. The azimuth angle $\hat{\theta}$ is measured in grads to the right of Easy (fig. 2, equation 2). The elevation angle ϕ is measured in grads below the horizontal. The quality codes K_θ and K_ϕ following the values for the angles indicate the estimated error: 0 for 0.0030 grads, 1 for 0.0060, 2 for 0.0090, and 3 for 0.0120. The instrument height h is in mm above the altitude of the survey station.

Apparently incorrect values from New Gilbert for θ are marker #3 at t = 27.367, #6 at 27.374, #7 at 26.674, #10 at 40.702, #19 at 26.872 and 27.901, #20 at 27.756, and for ϕ are #2 at 20.833 and 28.372, #3 at 20.826, #6 at 25.910, #7 at 20.744 and 28.376, #8 at 25.884, #14 at 28.385, #15 at 27.398, #16 at 28.374; those from New Quickie for θ are #1 at 28.872, #4 at 28.876, #7 at 28.880, #11 at 27.520, #12 at 29.547, #13 at 28.875, #14 at 28.874, #15 at 29.556 and for ϕ are #12 at 26.531, #15 at 26.521.

Appendix 2. Laser-measured distances to marker 11.

The time shown $\hat{t}$ is 200 less than the 1984 Julian Day, which is 214.0000 at 0000 hours on August 1, 1984 and increases by 1 each day thereafter. The actual measured distance $\hat{r}$ and the distance r adjusted for variation in atmospheric density are both 3 km more than the value that is given here in mm. Adjusted values for the first four readings are absent because of the unavailability of meteorological data then.

$\hat{t}$	$\hat{r}$	r	$\hat{t}$	$\hat{r}$	r	$\hat{t}$	$\hat{r}$	r	$\hat{t}$	$\hat{r}$	r	$\hat{t}$	$\hat{r}$	r
