1986
MAP AND DESCRIPTION OF THE METALLIFEROUS MINERAL DEPOSITS IN THE
JUNEAU, TAKU RIVER, ATLIN, AND PART OF THE SKAGWAY QUADRANGLES, ALASKA

By D. Edward Wells, Tom L. Pittman, David A. Brew, and Susan L. Douglass

The map and descriptions contain location and other information pertaining to mines, prospects, mineral occurrences, and mining claims in the Atlin, Juneau, Taku River, and part of the Skagway 1:250,000 quadrangles. The purpose of this report is to provide a background of current and historical mineral deposit data that will be integrated with other geological, geochemical, and geophysical data in a mineral resource appraisal.

This information has been compiled from numerous sources ranging from old, poorly documented accounts to modern comprehensive reports. When possible, original names and descriptions have been integrated with more recent information. Some previous compilations (by Berg and Cobb, 1967; Berg and others, 1981) are in general not used, as these are based on original material cited here. Cobb's (1972a,b,c) maps are cited, however, because of their value in readily locating specific sites. Similarly, Cobb's (1978a,b,c) summaries are cited, because of their specific mention of previous reports. During July and August, 1983, less than 10 percent of the reported sites, but including most of the mines, were located and sampled. Most underground workings were inaccessible. Dense vegetation and poor exposures restricted the work to brief examinations of exposed portions of these sites and limited the sampling. No attempt is made to evaluate the extent, grade, or economic significance of these deposits, although production and grade figures from the literature are reported.

Symbols shown on the map differentiate the productive mines, non-productive mines, prospects, mineral occurrences and claim groups. Much production went unrecorded and many inaccuracies undoubtedly exist. When a site fits more than one category, mines, prospects and mineral occurrences take precedence over claim groups. Productive mines are defined as mines with any recorded production or measured reserves. They are subdivided into mines with 500,000 tons or more of ore, those with 50,000 to 499,999 tons of ore, those with 10,000 to 49,000 tons of ore, and those with less than 10,000 tons of ore produced or measured. Productive placer mines are classified by assuming a 2 cubic yards = 1 ton ratio, or 150 cubic yards = 1 troy ounce of gold produced. Non-productive mines are defined as deposits with significant underground workings but no recorded production. They are subdivided into mines with 1,000 ft or more of underground workings and those with 500-999 ft of underground workings. Mineral occurrences are generally sites where metallic minerals have been observed, collected, and analyzed; but a few stream sediment and bedrock geochemical samples in published reports are also included. Several of these entries are probably almost meaningless from a mineral resources viewpoint, but have been included because they appear in the literature. Prospects are defined as any other areas with known surface or underground workings. Claim groups are subdivided into groups with 10 or more claims and groups of less than 10 claims (either lode or placer).
EXPLANATION OF THE DESCRIPTIONS

Map Number and Location

The upper right hand corner of each description sheet lists the map number of each site. The latitude and longitude are listed under "map coordinates." The locations are numbered separately for each quadrangle more or less sequentially in geographically defined groups. The descriptions are in this order: Atlin, Juneau, Skagway, Taku River.

The symbol at each site is centered on the major workings, group of workings, prospect, or a claim block. Where prospects or mine workings cover a relatively large area the range of latitudes and longitudes is given. Placer workings are distinguished by either a line along the stream or by a 'p' placed next to the symbol. Scattered sites of a single prospect or property are in some cases shown as individual locations with a, b, c, etc., but have identical map numbers. Irregular or discontinuous claim blocks are represented with symbols in the center of each significant portion of the block; the symbols generally have different numbers. See "Names," below, for discussion of how some claim blocks are related to individual mines or prospects.

Many of the sites were plotted from information sources accurate only to the nearest mile. Considering this, the rugged topography, and dense vegetation, such locations are only general guides to the sites described. In the table, coordinates for these sites are reported only to the nearest minute or may be designated "approximate."

Name(s)

The informal name of each site is listed next. When several claim names apply to one site, either the most recent, the more widely known one, or a name related to a topographic feature, is given. In a few cases where several prospects exist at one location, all are listed. Alternative names are given in parentheses. Claim groups of different ages and overlapping claim blocks are also treated in this way.

There is a problem in describing individual mines or prospects in relation to claim blocks. Although some individual mines and prospects are on small claim blocks and thus both can be readily located with a single symbol, others occur within large claim blocks and usually not near the symbol used to mark the center of those blocks. We have tried to minimize the possible confusion by treating the large blocks and their included claims differently than those small blocks and workings easily shown with a single symbol. Large blocks are named "Claim block: Big Sore, Lil Sore, Lode Star" etc., with the names taken directly from the ADGGS (1982) index. Individual workings within such a block are named without the prefix "Claim block."

An alphabetical index of "non-claim" sites follows at the end of all of the descriptions.

Claims

If claims are present, the number is listed for each site. An asterisk
(*) denotes patented claims. Lode and placer claims are distinguished by either (L) or (P). Where separate claim groups are recorded, the size of each group is listed. Several individual sites shown on the map lie within large claim groups and in some cases claim groups may overlap. For this reason the name and size of a given group may be listed for more than one site. Additional information may be obtained from the KARDEX listing maintained by the Alaska Division of Mining (ADM) Office, 794 University Avenue, Fairbanks, AK 99701, or from the ADM office at 400 Willoughby Ave., Juneau, AK 99801.

Resource

The mineral commodities of each site are listed by their chemical symbol or other convention. Precious metals are generally shown first, followed by other elements in order of known abundance. Elements present in trace quantities are shown in parentheses. REE indicates rare earth elements. Where queried, resources are inferred or uncertain.

This information is intended to communicate only that certain elements or combinations of elements are present at each site. No measure of the absolute amounts of the elements is intended.

Form

The morphology of the deposit at each site is given next. Where queried, the form is unknown.

Production/Reserves

The published amounts of materials mined, milled or produced are listed, and measured or inferred reserves are also given. Production is noted first as either short tons (T) of ore and(or) ounces (oz), accompanying grades are given; these are followed by references. If reserves are present, that information is then presented, following the same arrangement. Reported grades are shown either as percentages or as parts per million (ppm). The information is usually uncertain and may be incorrect. No firm estimate of past production or existing resources is intended.

Brief Description

The description is a concise summary of the geologic information obtained from various published sources or from a brief examination of the site. Original terms and measurements have been retained as much as possible. When conflicting or dissimilar terms were used by different authors, the most recent description was favored. Modern terminology has been substituted in some cases.

The extent of known workings is stated, although most are inaccessible and the sources may be inaccurate.

Claim groups are listed with the initial and last known year of activity.

A description of samples taken and the analytical results are given near the end of some descriptions. Samples were analyzed by atomic absorption and semiquantitative emission spectrometric methods. The results of the limited
sampling done during this work may not agree with previous reports and no quantitative estimate of resources or grade is intended.

Status

This refers to the present work. If the locality was not visited, then no entries are given after the words "located," "workings," "sampled." If the locality was visited, then appropriate entries follow.

References

This column lists, in chronological order, the references used in the compilation of the tables. The complete references are given below. Page numbers are given to simplify the reader's task in locating information. U.S. Geological Survey Open-File Report 84-564 (Douglass and Cobb, 1984) is a complete bibliography for the Juneau project area.

Abbreviations

ADGGS - Alaska Department of Geological and Geophysical Surveys
ADM - Alaska Division of Mining
ATDM - Alaska Territorial Department of Mines
oz - troy ounces
ppm - parts per million (34.28 ppm = 1 Troy ounce per short ton)
T - short ton(s)
USBM - United States Bureau of Mines
USGS - United States Geological Survey

Acknowledgments

We thank R. L. Elliott for a very careful and thorough review of a very preliminary manuscript, and W. M. Trollman for patience and care in too many revisions of the typescript.

RESOURCE (in order of abundance, if known): Zn, Cu, Barite (Ag, Sr)

FORM: Disseminated, strata-bound

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Two mineralized areas approx. 1/2 mi apart. Northern area contains iron-stained zones hundreds of ft wide and as much as 1,000 ft long in Permian andesite. Disseminated and small pods of pyrite contain 140 ppm Zn, 30 ppm Cu, 80 ppm Pb, 50 ppm Mo, .05 ppm Au over wide areas. A second location in altered Permian limestone near the andesite-limestone contact contains an 8 ft wide iron-stained zone with pyritic chert and minor amounts of chalcopyrite, sphalerite, silver and gold, ankerite, barite, celestite, strontianite, and wetherite. A sample contained 4.5% Zn, .19% Cu, .5% Ba, and 7 ppm Ag. Mineralization is discontinuous and may be remobilized. Other iron-stained zones nearby

NO. OF CLAIMS (*-patented, L-lode, P-placer): 30 L, 20 P

RESOURCE (in order of abundance, if known): Cu, Zn, Pb, RE

FORM: Disseminated, vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Country rock is metamorphosed Paleozoic volcanics and sediments intruded by a porphyritic Tertiary quartz monzonite. Mineralization consists of veinlets and silicified zones which contain micas, feldspar, iron oxides, pyrite, illmenite, and minute amounts of euxenite and thorianite. Samples contained up to 0.2% eU, and traces of Th and Nb (Matzko and Freeman, 1963). Explored by shallow pits and at least one drill hole. Nearby disseminated pyrite, arsenopyrite, and chalcopyrite occur in cherty rocks. Rock chip and grab samples of vein material contained 3,000-5,000 ppm Ba, 200 ppm La

RESOURCE (in order of abundance, if known): Au, Ag(Cu)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
200 T; 48 oz Au; 20 oz Ag (Mertie, 1921)

DESCRIPTION: Greenstone flows and tuff host a N80°E-striking, 70°S-dipping quartz-calcite breccia vein with chalcopyrite, pyrite, and traces of gold and silver. Ore produced was about 8% sulfides. Remaining material contains 2% Cu or less. Vein pinches and swells, contains veined and altered horses, and is offset by many small displacement faults. A similar, smaller vein is reported nearby. Development 1915-23, with a total of 2,400 ft of workings, most ore from 3 small stopes. Samples of calcite veins with quartz (10-20%), pyrite (1-3%), and chalcopyrite (1-2%) contained .5-1% Cu, .5% Zn, 10-15 ppm Ag

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
10,000-15,000 oz Au, together with Alaska-Dano and Hawk Inlet properties (Berg and Cobb, 1967)

DESCRIPTION: Country rock is jointed, folded greenschist, quartz-mica schists, graphitic phyllite, marble and minor aplite and albitized diorite intrusives. Quartz fissure veins crosscut foliation, trend NE, dip SE. Some stringers and thin pyrrhotite seams follow the foliation. Numerous parallel veins range from 3-10 ft wide, average 3 ft wide, and consist of white quartz, vitreous quartz, albite, carbonate, and varying amounts of quartz-chlorite. Sulfides are pyrite, pyrrhotite, galena, and minor sphalerite and chalcopyrite. White quartz usually has low gold values; free gold is associated with sulfides, especially sphalerite, and clear, vuggy quartz. Schists adjacent to veins also contain free gold and sulfides. Development 1894-1936 of over 3,000 ft of underground workings

LATITUDE (N): 58°14'30"
LONGITUDE (W): 134°51'00"
NO. OF CLAIMS (*-patented, L-lode, P-placer):

RESOURCE (in order of abundance, if known): Cu, Ni, Co

FORM: Disseminated, vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
Reserves 500,000 T, 4,000 ppm Cu, 4,500 ppm Ni (Noel, 1966)
Recovery tests 3,000 ppm Cu, 2,600 ppm Ni, 700 ppm Co (Berg and Cobb, 1967)

DESCRIPTION: Country rock is intensely folded quartz-mica schist, green-schist and phyllite striking NNW, dipping East. An irregular elliptical gabbro pipe 60-200 ft in diameter intrudes the schist, plunging 30° S, 80° E. Traces of disseminated pyrrhotite and pyrite and thin quartz lenses occur in the quartz-mica schist within 20 ft of the pipe. A 50-150 ft wide orthoclase=cordierite hornfels surrounds the gabbro. Most of the pipe is a gray, massive, fine- to medium-grained labradorite-augite-gabbro or norite with traces of sulfides and hydrothermal alteration. An area 360 ft by 60 ft by 40 ft along the lower edge or keel of the pipe consists of olivine-hornblende-labradorite-augite gabbro with 27% pyrrhotite, 2.6% pentlandite, 2.5% chalcopyrite, and 0.4% pyrite. The pentlandite and chalcopyrite exist as rims and interstitial grains around the pyrrhotite. Some of the Ni-Cu probably exists as exsolutions or as lattice constituents in the pyrrhotite or olivine. Minor amounts of secondary hornblende, micas, magnetite, talc and serpentine are associated with the sulfide-bearing gabbro. Extensive exploration by the Defense Exploration Administration 1951-56 with over 1,000 ft of workings and 6,000 ft of drilling

RESOURCE (in order of abundance, if known): Au, Ag, Pb, (Cu, Zn)

FORM: Vein

DESCRIPTION: Numerous veins near a granitic intrusive in quartz-mica schists, and chlorite and graphitic schists strike N 10-20° W, dip NE parallel to regional strike. One vein ranges from 15-25 ft wide and has been traced for over 2,300 ft. It is locally well mineralized, with pyrite, pyrrhotite and minor amounts of galena, specular hematite and free gold. Another vein is 30 in. thick, consists of white quartz with pyrite, specular hematite and minor amounts of chalcopyrite, galena, and copper oxides. It is crosscut by a calcite vein. Developed by two shafts (?) and an unknown amount of drifting, many open cuts

NO. OF CLAIMS (*-patented, L-lode, P-placer): 30 L

RESOURCE (in order of abundance, if known): Ag, Au, Cu, Pb, Zn

FORM: Vein

DESCRIPTION: Country rock is quartz mica schist, graphitic phyllite, intermediate intrusive rocks and minor slate. The units trend NW, dip steeply NE. The mine area has two sets of persistent fractures which strike N-S and N 20°-40° E and dip steeply E. Quartz veins, 10-50 ft wide and 500 ft or more long, follow the fractures. The Williams vein is 20-50 ft wide, 500 ft long and has at least 200-400 ft vertical extent. It is composed of both white, massive, barren quartz and bluish, friable quartz with pyrite, and rare pyrrhotite, chalcopyrite, galena, sphalerite and 1-34 ppm gold and silver. The vein is bound by gouge and the hanging wall is impregnated with 1-5% pyrite over a 6+ ft width. The quartz is fractured and filled with late quartz, calcite and sulfides. Development 1923-40 of several hundred ft of workings and a glory hole. All production from the Williams vein. Much trenching and minor workings on 10 other veins within 1,500 ft of the mine. Two 6-12 ft samples collected in 1983 in the glory hole contained 1-5 ppm Ag and traces of Au, Pb, Zn

RESOURCE (in order of abundance, if known): Zn, Pb, Ag (Barite, Cu, As)

FORM: Disseminated, vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Country rock is greenschist, quartz-muscovite schist and minor calc-silicate. Zones in schist contain disseminated pyrite and pods of pyrite in an area several hundred ft wide. Three E-W trending mineralized zones 25-75 ft wide contain quartz-carbonate-marioposite with 1-6 in. ribbons of pyrite, sphalerite, and galena with minor silver and gold. Previous samples averaged about 1-2% Zn and minor Pb, Ag, Au over a width of several ft (WGM, 1980). Developed by a 165-ft adit and several prospect pits. Recent prospecting resulted in a reported magnetic anomaly.

A 4.5 ft sample collected in 1983 contained 2% Zn, .5% Ba, 280 ppm As and a 8.1 ft sample contained 1,100 ppm Zn, 320 ppm As, .65 ppm Au

RESOURCE (in order of abundance, if known): Zn, Pb, Cu, Ag, Au, (Sb, Bi)

FORM: Massive, disseminated

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
Reserves 3.5 million T, 10% Zn+Pb+Cu, 410 ppm Ag, 5.5 ppm Au (Reed, 1983); 2 million T, 7-10% Zn, 2.5% Pb, .5% Cu, 344 ppm Ag, 3 ppm Au (Dressler and Dunbire, 1981)

DESCRIPTION: Distal volcanogenic massive sulfide deposit along a NW-trending argillite-tuff unit-volcanoclastic unit contact. Deposit is near the nose of an overturned anticline in (possibly) Upper Triassic units. Massive, banded Zn-rich ore occurs in 5 stratiform pods which average 11 ft thick. Disseminated and veined pyrite, pods and veins of quartz-pyrite, and chalcopyrite-bornite veins are stratigraphically below(?) these pods. The amounts of quartz and pyrite locally increases near the massive ore. White chert and barite-rich zones with high Ag, Au values occur on the ends of the massive ore zone. Mineralization includes pyrite, sphalerite, galena, chalcopyrite, bornite, pyrrhotite, tetrahedrite, bournonite and Ag,-Bi sulfosalts. Sericite, chlorite, talc, and mariposite are present in the tuffite below the mineralization. Active development and exploration, including (as of 1983) a 4,244-ft adit, a 400-ft crosscut and 67,000 ft of drilling. Mining is planned beginning in late 1986

NO. OF CLAIMS (*-patented, L-lode, P-placer):

RESOURCE (in order of abundance, if known): Au (Ag, Pb)

FORM: Stockwork

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
12,000 T; 5-7 ppm Au (Knopf, 1911a); 500,000 T combined reserves (Eakin, 1918)

DESCRIPTION: Ore bodies are stockworks of quartz veins in high-angle zones of sheared and chloritized diorite. Mineralization is dominantly pyrite with some chalcopyrite and rare galena. The pyrite varies from disseminated euhedral crystals to massive veins as much as 1 ft wide. Gold values coincide with pyrite, only 5% of ore was free-milling. Alteration varies with the intensity of veining, and includes chlorite, epidote, sericite and locally K-feldspar. Gangue is dominantly quartz with lesser amounts of carbonate and albite. The Kensington lode is a generally N-trending, elliptical stockwork 160 ft by 80 ft, dipping 60° E, with a vertical extent of over 1,000 ft. The veins are irregular, 1 in-1 ft wide and generally parallel the stockwork boundaries. The Eureka lode occurs several hundred ft west of the Kensington, with an outcrop length of 400 ft and a width of 30-40 ft at a depth of 350 ft. Production before 1901, considerable development 1904 and 1911-16. A 5,000-ft tunnel connects the Eureka, Kensington, Northern Belle and Johnson veins. Active exploration

RESOURCE (in order of abundance, if known): Au

FORM: Stockwork, vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: A stockwork of quartz stringers trending generally N15°W, dipping steeply E, with abundant pyrite in shattered diorite along the diorite, meta-amygdaloidal basalt contact. Sampling indicated a 1,500-ft by 50-70 ft body of close- to wide-spaced quartz stringers and veinlets with abundant pyrite, grading into widely spaced, lower grade veins. Vertical extent is probably a minimum of 400-800 ft. Connected by Kensington crosscut about 1913 and explored by 1,600 ft of drifts and crosscuts and numerous open cuts

RESOURCE (in order of abundance, if known): Au

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references): 23,000 T; (Wright and Wright, 1906)

DESCRIPTION: Quartz vein in diorite along the diorite-greenschist contact. The vein trends northerly, dips steeply to E, and is 2-10 ft wide. Gold associated with sulfides, but was apparently 78% free-milling. Reported grades of 1-5 ppm Au, ore shipped averaged 24 ppm Au. Production 1896-97. Orebody similar to the Comet mine.

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
50,000 T; 22,250 oz Au; (Wright and Wright, 1906)

DESCRIPTION:
Quartz fissure veins in diorite near and almost normal to contact with slate and graywacke. Major vein strikes N5°E, dips 70°E, is 2-9 ft thick, averages 3 ft, and 300-500 ft long, contains diorite inclusions. Vein is faulted off to north. Sulfides are pyrite, chalcopyrite and galena. Gangue is quartz with minor carbonates and feldspar. Gold occurs in rich pockets, as much as 107 ppm, and is closely associated with sulfides; grade averaged about 15 ppm. About 87% of gold is free. Over a mile of workings with a vertical extent of 650 ft. Mine operated from 1894-1901. Production was probably greater than reported. Later consolidated with Kensington and Bear properties. Active exploration

RESOURCE (in order of abundance, if known): Au (Cu, Pb, Zn)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
48,375 oz Au (Cobb, 1978a)

DESCRIPTION: Country rock is fine grained chloritized diorite, 1,200 ft from the contact with slate and greenstone. Three major and two minor quartz-carbonate veins trend NW to NNW, dip steeply E, across a 100-300 ft wide chloritized shear zone. The veins are irregular, braided, and pinch out into shear zones. They range from 1-10 ft wide, average 5 ft, 400-600 ft long, with at least 600 ft vertical extent. Well-mineralized quartz stringer lodes occur where veins change strike. Mineralization is dominantly pyrite with lesser amounts of chalcopyrite, minor galena and rare sphalerite. Gold is 80% free-milling, 14-53 ppm in veins (averaged 20 ppm). Some reported silver assays, yielding 2.8 to 1 Au:Ag ratio. Gangue is quartz with ankerite and some calcite. Diorite is pervasively chloritized with local sericite and epidote. Production 1896-1920 from 3 veins. More than 18,000 ft of workings including a 5,500 ft haulage and dewatering tunnel (not completed) beneath the veins. Active exploration

145 oz Au from Rex; (Spencer, 1906)

DESCRIPTION
Five closely-spaced properties, as follows:
Dividend: quartz-calcite stringer lode in graphitic slate above a greenstone (augite melaphyre) footwall. Stringer zone is 12-16 ft wide with pyrite, arsenopyrite, galena, and gold. Developed by 1,200 ft tunnel and 250 ft drift.
Rex: small, irregular calcite-quartz vein with auriferous arsenopyrite in greenstone.
Noonday: 1 6-ft wide quartz stringer lode in graphitic slate and schist.
Puzzler: a 14-ft wide quartz stringer lode in graphitic slate and schist.
Julia: quartz stringer lodes, 8 and 12 ft wide in slate.

NO. OF CLAIMS (*-patented, L-lode, P-placer): 152 L

RESOURCE (in order of abundance, if known): Au (Cu, Pb, Zn)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
23,000 oz Au; Berg and Cobb, 1967

DESCRIPTION: Quartz veins in shattered slates which contain minor thin sheets of mafic intrusive rock. Ore shoots in veins are 5-15 ft wide, 25-100 ft long, strike N30°W, dip 50°NE, and plunge 30°NW. Veins contain pyrite, arsenopyrite, pyrrhotite, galena, sphalerite, chalcopyrite, native copper, and free gold. Best gold ore associated with sulfides, especially arsenopyrite and galena; also in yellow, honeycombed quartz. Grades were as much as 50-34 ppm Au, average production was probably 17 ppm Au. Ore body offset by numerous fault zones. Slate disrupted by landsliding and surface creep. 30,000 ft of workings, most production 1903-10. Some exploration 1913-30. Numerous adits and prospects in area. Claim blocks extend to Cascade, Olson, and Dividend (?) areas

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
22 Tons; 11 oz Au; (ATDM, 1937)

DESCRIPTION: Discontinuous, NW-trending quartz stringer lodes and lenses usually less than 12 in. wide; in chlorite schist, graywacke, slate, and greenstone. Part of a discontinuous zone of weak quartz veining between Montana and Windfall basins. Veins contain arsenopyrite with some intergrown galena and gold, and traces of sphalerite, pyrite, and chalcopyrite. A high grade sample assayed 1.6% As, 22 ppm Au, 2 ppm Ag, and traces of Sb. Developed by 3 tunnels, over 500 ft total length. Adjoins Windfall Creek. Several prospects along strike; included in references to Patton prospect and Montana Creek

RESOURCE (in order of abundance, if known): Au (As, Pb)

FORM: Vein, disseminated

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: A 50 ft x 800 ft hanging wall portion of a greenstone sill is fractured, brecciated, and filled with quartz veins as much as 1 ft wide. The veins trend N70°-80°W, are dominantly quartz with albite, calcite, chlorite, and sericite. Arsenopyrite is the major sulfide, with pyrite disseminated in the sill. Pyrrhotite and galena are present in the Treasury Hill (southern) claim. Some apparently barren vein material contains up to 4 ppm Au, altered dike rock about 1-2 ppm Au (Knopf, 1912). Nearby large quartz masses contain small amounts of arsenopyrite, pyrite, and free gold. Sampling yielded only traces of As, Au. At least 3 separate prospects developed by open cuts and short adits

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
2,500 T?; 3-5 ppm Au; (ATDM, 1937a)

DESCRIPTION: Several ounces of gold recovered by sluicing overburden. Several 1-2 ft quartz veins in altered greenstone (tuff and volcanic breccia) near slate contact. Discontinuous veins and irregular masses of quartz form a network of intersecting fracture fillings which trend N to NW, dip NE. The entire mass forms a stringer lode 35 to 200 ft wide, unknown length. Mineralization consists of milky quartz, calcite, and sericite with pyrite, arsenopyrite, pyrrhotite, galena, and traces of chalcopyrite and tourmaline. Several open cuts, most work before 1917

RESOURCE (in order of abundance, if known): Au (Ag)

FORM: Placer

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: A gravel deposit 4,000 ft long, as much as 700 ft wide and a maximum of 90-100 ft thick. The deposit formed when an ancient landslide dammed Gold Creek, forming a temporary lake in a glacially scoured basin and causing rapid gravel accumulation. The upper end probably contained the higher grade material. In 1897 a 2,000 ft tunnel was driven to wash the deposit but failed to reach the bedrock floor. Considerable difficulty was caused by the presence of the landslide debris. Operations were probably not profitable. Amount of production unknown, probably less than 500 ounces. See also Gold Creek, Silverbow Basin, Lurvey

RESOURCE (in order of abundance, if known): Au, Ag, (Cu, Barite, Pb, Zn)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
29,000 oz Au; 3 ppm Au (Spencer, 1906)

DESCRIPTION: Northern end of A.J. System. A zone 1,500 ft wide (800 ft on Humbolt), 1,100 ft long with 3 meta-gabbro dikes intruding slate. Mining dimensions were about 60-90 ft wide, 200-300 ft long, and 300-500 ft vertical extent. Cleavage and bedding strike N58°W, dips 70°NE. The dikes and slate are cut by 1-2 ft veins and numerous stringers, especially along the dike-slate contact and 20-30 ft into the dikes. Veins generally parallel strike and dip both with and normal to the host units. The dikes contain the most and more closely spaced veins, in intensely veined areas they are altered brown and contain auriferous pyrite and some magnetite. Gangue minerals are quartz and carbonates with minor amounts of sericite, biotite and tourmaline. Pyrrhotite is the principal sulfide with galena, sphalerite, pyrite and chalcopyrite. Most gold occurs as free, coarse flakes in the veins. Rock chip samples contained .2-.5% Ba, .1-.3% Cu, 1-2 ppm Ag, and as much as 12 ppm Au. Development was by 4,000 ft of underground tunnels, raises, and numerous stopes. Most production was 1888-1905, joined to A.J. System in 1925

RESOURCE (in order of abundance, if known): Au (Ag)

FORM: Placer

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
Total all placer production 63,280 oz Au; (Spencer, 1906)

DESCRIPTION: In general, placer gold occurs throughout Gold Creek, its tributaries, and on the slopes below the lode zone. Some low grade accumulations of gold are present in the glacial moraines. Fine gold must be present at the mouth of Gold Creek and in Gastineau Channel. Three types of materials were mined, 'hill' placers of weathered residium on and just below the lodes, 'gulch' placers which are the result of mass wasting of the lodes that collected in the small drainages, and stream placers which formed in ancient lake basins and the present streams. Placer mining began in 1880, most production 1881-1903, mining continued intermittently through 1940. See also Silverbow Basin, Last Chance Basin, Lurvey

Little Basin is a small parallel valley in Gold Creek with several acres of gravel averaging 20 ft deep. The upper end was worked before 1903. Operations could have been hampered by tailings and the lack of drainage

Middle Flat is a low grade gravel accumulation 2,500 ft long, 100-200 ft wide and varying thickness

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
See Gold Creek

DESCRIPTION: Auriferous material derived from the lode zone was washed into a partially closed, post-glacial lake basin at the head of Gold Creek. A total of about 200 acres of material existed. About 20 acres averaging 75 ft thick was mined 1891-1903, yielding 16,000-19,000 oz of gold. The gold fineness averaged 802. Mined by driving a 3,400 ft tunnel in bedrock, gravel was washed in by hydraulic mining, and recovered by sluices in the tunnel. Some gold was recovered from weathered lode residium (hill placers) and some from lode material accumulated by slope wash (gulch placers). This basin produced most of the placer gold from the Juneau area, and was the only large-scale profitable placer operation. See also Gold Creek, Last Chance Basin, Lurvey

NO. OF CLAIMS (*-patented, L-lode, P-placer): 19* L, in part duplicates; claims noted under Ebner
RESOURCE (in order of abundance, if known): Au, Ag, Pb (As, Cu, Zn)
FORM: Vein
PRODUCTION AND RESERVES (Tons, ounces; grade; references):
88,466,078 T mined; 47,192,108 T milled; 2,888,296 oz Au; 1,949,810 oz Ag; 20,109 T Pb (Stone and Stone, 1983). Mineralized veins sampled in this study contain 0-340+ ppm Au; average 7-15 ppm Au
DESCRIPTION: The AJ lode system is part of a 1,000-2,000 ft wide zone in the footwall of the Perseverance slate, in and near intrusive metagabbro sills. The area of pervasive veining and mineralization is about 300 ft wide and 18,500 ft long. The ore zones occur as lenticular concentrations of quartz stringer lodes in faulted slate and also near the edges and within the altered portions of the metagabbro dikes. Ore was mined from 100-200 ft wide, 300-400 ft long stopes, for a vertical extent of 1,000 ft (south ore body) to 2,500 ft (north ore body). The transverse Silverbow fault separates the A.J. mine into blocks and offsets mineralization about 1,800 ft. Quartz veins are discontinuous, irregular, range from 1 in. to 2-3 ft wide and both parallel and slightly crosscut regional foliation. Veins are well-defined, consist of 95% quartz, 1-3% carbonates, traces of sericite, tourmaline and a maximum of 2-3% sulfides. Pyrrhotite is most common, accompanied by various amounts of pyrite, arsenopyrite, galena, sphalerite, and chalcopyrite. Gold is mostly fine and concentrated with the sulfides. Both gold and sulfides are concentrated in the center and on the edges of the quartz stringers. Mineralogic and elemental zoning is evident as pyrite, sphalerite, galena and locally arsenopyrite become more common in the southern ore bodies, silver also increases, the Au:Ag ratio changes from 7:1 (Ebner) to 1:1 (Perseverance). Discovery and initial mining of residual placers in 1880 was followed by lode production until 1944. Developed as a low grade operation, with miles of tunnels, and numerous slopes and glory holes. Stringer lodes were block-caved. Ebner mine was included in the A.J. system in 1924, the Perseverance mine after 1934. Total production listed includes material from these mines after acquisition. RESOURCE (in order of abundance, if known): Ag, Au, Pb, Zn (As, Cu)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
11,612,000 T; 500,900 oz Au; AgPbZn unknown (Twenhofel, 1952)

DESCRIPTION: South of and adjoining the Alaska-Juneau lode system. Unlike the main A.J. lode, amphibolite (metagabbro) dikes are smaller, less continuous, and do not host major orebodies. The relative amounts of Ag, Pb, Zn and As increase compared to the northern Alaska-Juneau system. The Au:Ag ratio is about 1:1. Thin quartz veins and stringer lodes form an ore zone in slate footwall along the slate-greenstone contact which strikes NW, dips about 60°NE, and slightly crosscuts foliation. Most mineralization is within the slate, with minor amounts of schist and metagabbro ore. The orebodies average 90 ft wide, and occur along strike for over 4,000 ft with a vertical extent of 2,000 ft. Sulfides (1-2%) are pyrrhotite (dominant) and arsenopyrite, galena, sphalerite, pyrite and chalcopyrite. Gangue is quartz with minor carbonate (ankerite and sericite) and traces of tourmaline. Mined on a large scale 1895-1921, with a maximum production of 150,000-200,000 tons a month during 1919. Ore recovery was as free gold and Pb-Au concentrates. The mine was included in the A.J. system after 1935. Nineteen miles of development, including a 10,500 ft adit (to Sheep Creek). Production figures given are for 1895-1921, unknown amount of production before 1895. Minor hillside placer production from the Groundhog area.

RESOURCE (in order of abundance, if known): Au, Ag (Cu, Mo, Pb, Zn, As, Sb, W, Sr, V)

FORM: Disseminated, vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
28.7 million T crushed; 3.2 million oz Au; average 4-5 ppm Au; amounts of Ag, Pb unknown; (Stone and Stone, 1983)

DESCRIPTION: Albite-diorite sills intrude a NNW-striking, NE-dipping greenstone-slate contact along a chlorite schist horizon. The sills are irregular, with numerous pinches and swells and contain septa of slate and chlorite schist. Six major 'dikes' and many smaller intrusions occur, varying from dark, relatively unaltered diorite to white, albitized, veined and pyritized diorite. Mineralization is disseminated in highly altered rock in .1 in.-6 ft veins in the slate and schist septa and in the footwall. Ore shoots were 60-100 ft wide, concentrated along the slate footwall and in swells as 20°-40° S-dipping bands. Pyrite occurs as disseminated cubes in veins and veinlets, and in .5-4 in. clusters. Minor amounts of pyrrhotite, molybdenite, chalcopyrite, magnetite and rutile are commonly associated with the pyrite, and rarely galena, and sphalerite. Minute quantities of realgar, orpiment, native arsenic and scheelite occur. Gold is disseminated, free, and associated with quartz-calcite veins, and with secondary albite and pyrite. Grades mined ranged from 1-2 ppm Au to rare 170 ppm shoots. Samples collected in 1983 contained 2-9 ppm Au, 0-1 ppm Ag, 0-.2% Cu and Pb. Placer mining began in 1881, lode mining in 1882. All four mines had interconnected workings which extended under Gastineau Channel. In 1917 the Treadwell, 700 Ft and Mexican mines flooded, but the Ready Bullion was worked until 1922, and minor surface work continued until 1926. The mined area is 3,500 ft long, as much as 400 ft wide and 2,000-2,800 ft deep with thousands of feet of workings and three major glory holes. No data on Ag, Pb production

RESOURCE (in order of abundance, if known): Ag, Au, Pb, Zn (Cu, As, Co, Bi)

FORM: Disseminated, vein

DESCRIPTION: Country rock is phyllite, greenstone agglomerate and intercalated slate. Deposit is part of a 1-mile wide, 1.5-mile long area of alteration and mineralization. Mine area is centered on sericitized and silicified phyllites and felsic meta-volcanic units about 90 ft wide and 2,000 ft long. Mineralization consists of narrow bands of quartz-sericite-pyrite (1%) both in quartz-feldspar-carbonate veinlets and as disseminated auriferous pyrite. Sulfides are: Pyrite, chalcopyrite, galena, sphalerite, pyrrhotite, and tetrahedrite(?). Mining and development before 1915 resulted in 3,650 ft of workings, 365 ft of which was in ore. Grab samples taken in 1983 of sulfide-bearing schist averaged 1% Zn, with some Pb, and .65-1.5 ppm Au. Prospecting in late 1960's. Claims patented 1929, current claims. DESCRIPTION: Country rock is hornblende schist and mafic garnet gneiss with rare, thin quartz diorite and basalt dikes. Several 1-3 ft wide, quartz veins and thin quartz stringers in brecciated zones strike NE and dip steeply NE. Mineralization occurs both disseminated in breccia and as 2nd stage vein replacements. The larger veins may be traced as much as 300 ft and end at minor faults. Sulfides are pyrite, arsenopyrite, stibnite, and some sphalerite and galena. Numerous samples indicate a Au-Ag ratio of about 1:10 or greater (ATDM, 1940). Developed by numerous open cuts, 2 adits and a 150 ft crosscut. Samples collected in 1983 of veined shear zones contained .1-1% As, 15-100 ppm Ag, as much as 7 ppm Au. High grade veins contained .5-1% As, 15-500 ppm Ag, one sample contained 70 ppm Au

NO. OF CLAIMS (*-patented, L-lode, P-placer):

RESOURCE (in order of abundance, if known): (Au, Ag, Cu)

FORM: Disseminated

DESCRIPTION: Brew and others (1978) report that "Arsenopyrite, chalcopyrite, pyrite, pyrrhotite and traces of gold occur in ankeritic zones near an irregular, interfingered contact that marks a facies change between marble and phyllite. About 10 separate zones are present and each is less than 10 ft wide and less than 100 ft long. The zones are copper- and iron-stained and are conformable with the bedding of the metasediments. One zone forms the hanging wall of a 5-ft-wide andesite dike that contains chalcopyrite and pyrite. A 2-ft channel sample taken across an iron-stained zone in marble contained 0.003 oz Au per ton, 13,000 ppm Cu, 200 ppm Zn ..., 15 ppm Ag, 7,000 ppm As, 5 ppm Mo and greater than 5,000 ppm Mn. Four other channel samples, ranging in length from 1.0 to 2.4 ft, taken across similar zones in marble contained from 20 to 55 ppm Cu, from 10 to 80 ppm Zn ... and N to 10 ppm Mo. MacKevett and others (1970) report that a select grab sample of sulfide-bearing rock contained 0.088 oz Au/ton ... 7,000 ppm As and 150 ppm Cu. A 2-ft channel taken across an ankerite zone contained 0.0088 oz Au/ton ... and 100 ppm Cu."

RESOURCE (in order of abundance, if known): Fe, Ti, V (Ni, Pt-Pd)

FORM: Magmatic segregation

PRODUCTION AND RESERVES (Tons, ounces; grade; references): No production. 13 billion tons of reserves containing 0.2 % V₂O₅ (Fischer, 1975), 13 % magnetic iron (Berg and Cobb, 1967), 1.5-4.4 % TiO₂ (Wells and Thorne, 1953)

DESCRIPTION: Several tabular zones of titaniferous magnetite in pyroxenite surrounded by diorite; magmatic segregation with magnetite interstitial to pyroxene and idiomorphic against hornblende. According to Taylor and Noble (1969), the titaniferous magnetite is fairly uniformly distributed through the pyroxenite and makes up 15-20 percent of the rock. Other constituents are small amounts of chalcopyrite, hematite, pyrite, pyrrhotite, spinel, and leucoxene. Samples also contain as much as 0.11 % P, 0.03 % S, and 0.03 % Ni

Cobb, 1978c, p. 92,93
NAME(S): Klukwan Fan

LATITUDE (N): 59°24'36"
LONGITUDE (W): 135°53'59"

NO. OF CLAIMS (*-patented, L-lode, P-placer): 134 P

RESOURCE (in order of abundance, if known): Fe, Ti, V (Ni, Pt-Pd)

FORM: Alluvial fan

PRODUCTION AND RESERVES (Tons, ounces; grade; references): No production. An estimated 500 million tons of broken rock (Robertson, 1956) with 10% titaniferous magnetite (Robertson, 1956), 0.05% V₂O₅ (Fischer, 1975)

DESCRIPTION: Alluvial fan at foot of mountain slope below Klukwan Lode has radius of about a mile and an apex height of 700 ft. Deposits long known, but no great interest shown until after World War II. A few tons have been taken from the fan for metallurgical testing. It is made up of well mixed epidote diorite and pyroxenite in clasts that range in size from silt to large boulders. Claims, 1953-1967

FORM: Magmatic segregation(?)

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Pyroxenite apparently surrounds a small body of epidote granite and in turn is surrounded (with gradational contact) by metabasalt. Contains probably less than 10 % magnetite in grains as much as 1/4 in. in diameter. Ilmenite intergrown with magnetite; some apatite present. Resource estimated at several billion tons of material containing less than 10 % magnetite and 1.3-1.8 % TiO₂. Only exploration is 100-ft tunnel driven about 1906. Possible location of the tunnel plotted as S054.

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Freeman (1963) reports that a small, altered rhyolite (?)
body surrounded by faulted quartz diorite is intruded by
fine-grained andesitic dikes. Uranium is adjacent to a
steeply dipping fracture in rhyolite associated with iron-
oxide staining and globules of clay that resemble vesicle
fillings. Sample of clay contained 0.72 % eU and 1.2 % U;
only a very small amount of this material present. Mineral-
ized rock (iron-stained, altered rhyolite(?)) contains
as much as 0.22 % eU. No sulfides; a few specks of purple
fluorite

DESCRIPTION: A reported molybdenum prospect found by tracing float up Wright Glacier. A 4,500 ft x 5,000-6,900 ft diorite porphyry stock with sericitic, potassic, and chlorite alteration and minor quartz-breccia bodies hosts molybdenite as disseminated crystals (rare), and in miarolitic cavities, fractures, and quartz veins. Minor amounts of scheelite, fluorite, rhodochrosite, arsenopyrite, sphalerite, galena and gold are also reported in veins and breccia. Most mineralization is in Canada.

NAME(S): Sunrise Canyon, Slocum Inlet

LATITUDE (N): 58°04'30"
LONGITUDE (W): 133°55'05"

NO. OF CLAIMS (*-patented, L-lode, P-placer): 8? L

RESOURCE (in order of abundance, if known): Mn

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: A zone of schistose phyllites 200-300 ft wide strike N 50° W, dip 45°-85° NE, contain persistent 0.1-3.5 ft manganese-bearing veins over a 6,000-ft length. The veins contain rhodochrosite, manganese oxide, rhodonite and quartz. A channel sample 3.5 ft wide assayed 22% Mn, a 1.0 ft sample contained 32% Mn. Benefication tests failed to produce a marketable concentrate. Claims, 1935-1979

STATUS: Located:
Workings:
Sampled:

REFERENCES: Pittman, 1957
Cobb, 1972b, no. 4; 1978b, p. 49
USBM, 1973b, no. 1
NAME(S): Limestone Inlet, Enterprise, Arizona Group

LATITUDE (N): 58°02'45"
LONGITUDE (W): 133°58'00"

NO. OF CLAIMS (*-patented, L-lode, P-placer): 4 L, 8 P

RESOURCE (in order of abundance, if known): Au, Cu, Pb, Zn

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):

DESCRIPTION: Country rock is slate and greenstone which have been intruded by a porphyritic diorite. Two parallel sheeted quartz veins, average 2-3 ft wide (maximum 9 ft wide), and several hundred ft long, strike N 25° E, dip 45° NW. Veins contain free gold and minor amounts of galena, sphalerite, chalcopyrite and pyrite. A similar occurrence (Arizona group) is located a few hundred ft to the northwest. Developed by about 500 ft of drifts and a raise before 1916. Minor production? Claims 1880-1982

RESOURCE (in order of abundance, if known): Ag, Au, Pb, (Zn, Cu, As)

FORM: Vein

PRODUCTION AND RESERVES (Tons, ounces; grade; references):
1,808 ppm Ag, 57 ppm Au + Pb (Knopf, 1910)

DESCRIPTION: Quartz fissure veins in dolomite septum or pendant in diorite. Sulfides include arsenopyrite, pyrite, pyrrhotite, galena, sphalerite and chalcopyrite. Assay value given above is for a selected 17-in. sample. Veins are complexly faulted. One vein exposed along an 80-ft open cut is as much as 4-5 ft wide, others are much smaller. Development consists of open pits and one 75-ft tunnel. Claims, 1909-1982
