*Processing stages and plot format:

1) Uncorrected acceleration
2) Corrected acceleration, velocity, displacement
3) Relative velocity response spectrum, linear plot
4) Response spectrum, tripartite log-log plot
5) Fourier amplitude spectrum, linear plot
6) Fourier amplitude spectrum, log-log plot

In column 1 each plot contains all three components. For columns 2 through 6, the indicated page number refers to the first of three components for this record.
INTRODUCTION

The U.S. Geological Survey Permanent Strong-Motion Network

In a continuing effort to present processed strong-motion earthquake data to the engineering and seismological communities and the general public, the U.S. Geological Survey (USGS) maintains a nation-wide network of federally-owned permanent strong-motion earthquake recorders, and routinely processes and reports on significant records obtained from them. The network also includes instruments owned by other federal agencies, but maintained by the USGS. The production of reports is sometimes made jointly, for example with the California Division of Mines and Geology (CDMG), to coordinate records obtained simultaneously from the recorders of various other federal, state, and local agencies.

The main reasons for these reports are to present the computer plots of corrected accelerograms and their spectra, and to provide sufficient additional information on the earthquakes, stations, records, and results so that the reader may make an intelligent decision whether further study is warranted. Lists of completed reports and their contents are given in Appendix II. Digital data is usually available on tape from the National Geophysical Data Center (NGDC), NOAA, Mail Stop E/GC11, 325 Broadway, Boulder, Colorado 80303.

Cooperative Endeavors

The permanent strong-motion network is managed by several projects within the USGS. The program and its predecessors have been involved with strong-motion accelerogram recording and processing since the early 1930's. As procedures and techniques have improved within the areas of network planning, instrument maintenance, record processing, and associated research, the program has been able to exchange knowledge in cooperative efforts with other agencies in the field of strong-motion earthquake engineering and engineering seismology.
Cooperative efforts have included those with:

a) Federal agencies such as the Bureau of Reclamation, the Army Corps of Engineers, the Veterans Administration, the Federal Highways Administration, and others.

b) State agencies such as the California Division of Mines and Geology, the California Department of Water Resources, the Washington State Highways Administration, and others.

c) Universities such as the California Institute of Technology, the University of Southern California, Columbia University, and others.

d) Foreign and domestic agencies sometimes jointly responsible for strong-motion networks in Fiji, Greece, Italy, Papua New Guinea, The Soviet Union, Yugoslavia, and others.
PROCESSED RECORDS FROM THE JANUARY 1, 1975, 0355 GMT
SOUTHERN ALSAKAN EARTHQUAKE

Four stations from the slowly developing network in Anchorage, plus the station in Talkeetna, provided records from this MB 5.9 event. Previous Anchorage records had been lone ones, dating back to the aftershocks of the 1964 Prince William Sound, Alaska, earthquake. Under normal circumstances, this set, with peak values less than 0.1 g, would not have been digitized. Interest, and a request from the USGS in Golden, Colorado resulted in the processing of three ground level records in Anchorage, and the Talkeetna record. The fourth Anchorage record, from the Post Office, was not suitable for digitizing.

Description of Records

The peak accelerations (Seismic Engineering Branch, 1975) recorded were: Talkeetna (approx. 49 km epicentral distance) with a peak of 0.09 g; and of the stations in Anchorage (approx. 79 km epicentral distance) the largest peak was 0.09 g at the Methodist University. A complete list of peak values and other information for this event are in Table II.

Seismological Data

The January 1, 1975, 0355:12.0 GMT event occurred at a depth of 66 km and at a location of 61.9 degrees N. and 149.7 degrees W. This location is N of Anchorage and SE of Talkeetna. The magnitude was MB 5.9 (see Table I).

Station and Geologic Data

The following information (Switzer and others, 1981) briefly describes the accelerograph sites pertinent to this report:

Anchorage Stations:

500 West Third Street: A 22-story building with instruments in the basement and on the roof. Surficial geology is glacial outwash.
Alaskan Methodist University: A two-story building with the instrument located at ground level. Located on approximately 120 m of glacial till.

Government Hospital: A three-story building with the instrument located in the basement. Surficial geology is glacial outwash.

Talkeetna:

FAA-VOR Building: A one-story building with the instrument located at ground level.
DIGITIZATION AND PROCESSING

Current USGS Processing

1. A commercial digitizing firm (IOM-TOWILL in Santa Clara, California) digitizes the records on a trace-following, computer-controlled laser scanner. The data is digitized at unequal time intervals, (although close to equispaced in time when clear of sharp peaks), at an average of 600 samples per second (sps). Those records on 12" wide photographic paper are photographically reduced to 1/4 original size so that all three traces and the time marks can be digitized in one horizontal panel. Although the acceleration and time scales are reduced proportionately, a full-scale check of the digitized version matches perfectly with the original 12" record.

2. If more than 10 cm of a strong-motion record is digitized (film speed is 1 cm/s), the digitized portion is divided into approximately 10-cm frames and each frame is digitized separately with one inch overlaps. The frames are reassembled using specially inserted vertical lines; the lines mark the beginning and end of each frame. Each vertical line is digitized twice, once in each adjacent frame, and then used in reassembling the record.

3. The uncorrected data are prepared by subtracting the digitized reference traces from the data traces, by using the digitized time marks to determine the time scale, and by subtracting the mean. The instrument sensitivities scale the ordinates to acceleration.

4. The data are passed through a correction algorithm that applies a high-frequency, 50 Hz, low-pass filter; an instrument correction; a base-line correction in the form of a long-period (or low-frequency, high-pass) filter; and decimation to 200 sps. Plots of the corrected
acceleration, velocity, and displacement for the three components of each record are included.

Initial selection of long-period filters is based on the convention of retaining a period content greater than or equal to the strong-motion duration of the records. The final Butterworth filter parameters are chosen to eliminate any visible serious noise content still remaining in the calculated displacements, taking into account the guidelines described in Basili and Brady (1978).

In some instances a frequency domain filter with a transition band of 25-50 Hz is applied to eliminate high frequency noise that sometimes occurs during the digitization of low-amplitude records. The latter replaces the standard time-domain method.

5. The maximum relative velocity response spectra are calculated for damping values of 0, 2, 5, 10, and 20 percent of critical. These response spectra are calculated for a period range which commences at 0.04 s and ends with the long period limit used in the base-line correction algorithm. The dashed curve on this plot is the unsmoothed Fourier amplitude spectrum, calculated at the same periods as the response spectra are calculated.

The second response spectra plot contains the pseudo-velocity response spectra, calculated for the same five damping values. This tripartite plot also has the values for the maximum relative displacement response spectrum and the pseudo-absolute acceleration spectrum.

6. Fourier amplitude spectra, calculated by FFT, are presented on linear and log-log axes to accent the particular characteristics at each end of the spectrum.
For a more complete description of the processing method see Converse (1984).

Processing Considerations for Records in this Report

The first 2-3 seconds of the three data traces on the uncorrected record from 500 W. Third, Basement, have a non-zero start and similar downward slopes, indicating a problem with the subtraction of the reference trace. (The original record has no reference traces and the digitized time trace was used for both time trace and reference trace). In an unsuccessful effort to correct this problem, the data traces were processed with no reference trace (Fig. 3). Since these plots clearly indicate that the motion of the film through the camera must be corrected with a reference trace, even if less than ideal, we decided to use the original results and rely on the subsequent processing to make the correction.

Results/Summary

Appendix I contains reproductions of computer-generated plots which provide a visual description of the recorded accelerations and their processed results. These plots may be used to measure directly specific earthquake characteristics or record parameters and to select records for further study using the digital data.

ACKNOWLEDGMENTS

Modern digital processing of strong-motion accelerograms has evolved over many years, from the work of Trifunac and Lee at Cal Tech and of Virgilio Perez at the USGS, to the present ongoing refinements of the process in April Converse's AGRAM series. The authors acknowledge these and other contributions to strong-motion data processing.
