# CONVERSION FACTORS

Factors for converting inch-pound units to International System of Units (SI) are shown to four significant digits.

<i>Multiply</i>	<i>By</i>	<i>To obtain</i>
inch (in.)	25.4	millimeter (mm)
foot (ft)	0.3048	meter (m)
gallon per minute (gal/min)	0.06308	liter per second (L/s)
gallon per minute per foot [(gal/min)/ft]	0.2070	liter per second per meter [(L/s)/m]
microsiemens per centimeter at 25 °C ( $\mu\text{S}/\text{cm}$ )	1	micromho per centimeter at 25 °C ( $\mu\text{ho}/\text{cm}$ )

# CONSTRUCTION, GEOLOGIC, AND HYDROLOGIC DATA FOR OBSERVATION WELLS IN THE REELFOOT LAKE AREA, TENNESSEE AND KENTUCKY

*By Michael W. Bradley*

## ABSTRACT

Twenty-three observation wells were installed at 12 sites in the Reelfoot Lake area of Tennessee and Kentucky during July 1986. The wells were installed to supplement the existing water-level network and to provide additional data on the hydraulic characteristics and vertical hydraulic gradients in the alluvial aquifer near Reelfoot Lake. Well yields ranged from less than 20 gallons per minute to about 140 gallons per minute. Specific capacity ranged from less than 1 to 17.1 gallons per minute per foot of drawdown.

Three stratigraphic sequences were encountered during drilling. Clay and silty clay was about 40 feet deep near the southwest corner of Reelfoot Lake. Predominantly medium- to coarse-grained sand occurred below about 15 feet of silt and clay near the west and northwest sides of Reelfoot Lake. Along the western limit of the study area, near Lake No. 9 and the Mississippi River, about 20 to 30 feet of silt and silty sand occurred below land surface.

## INTRODUCTION

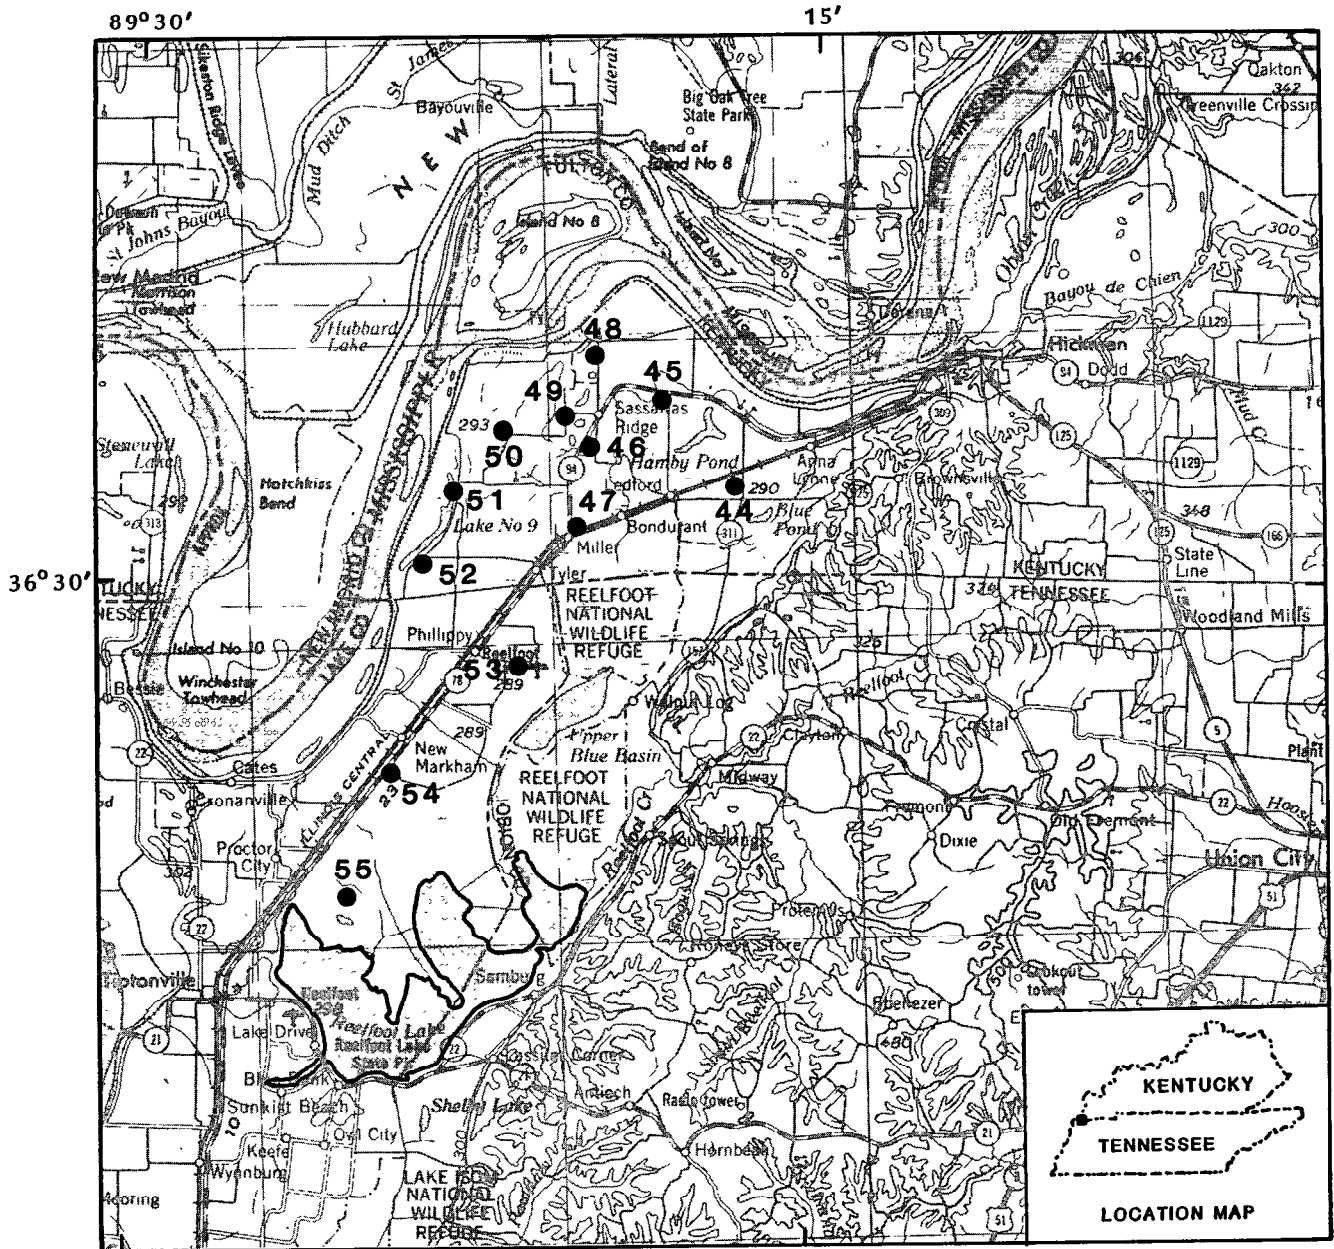

Reelfoot Lake in extreme northwest Tennessee (fig. 1) was formed during the New Madrid earthquake of 1811-12. Since that time the lake has been an important natural resource to Tennessee and adjoining states. Recently, the U.S. Geological Survey, in cooperation with the Tennessee Wildlife Resources Agency, began an investigation of the surface- and ground-water interactions and their effects on the hydrologic system of Reelfoot Lake. The study included the installation of 23 wells at 12 sites in the Reelfoot Lake area of Tennessee and Kentucky (fig. 1). These wells were

installed to supplement the original well network (Robbins and others, 1985) and to provide information on the vertical hydraulic gradient and the hydrologic characteristics of the shallow alluvial aquifer. The purpose of this report is to describe the construction of the wells, the lithology encountered, and the results of some short-term hydrologic tests conducted following well construction.

The Reelfoot Lake area of Fulton County, Kentucky, and Lake and Obion Counties, Tennessee, occurs in the alluvial valley of the Mississippi River. An escarpment formed by the loess uplands marks the eastern extent of the valley. The study area is underlain by unconsolidated loess, sand, silt, gravel, and clay. Formations present, in descending order are, loess, Mississippi River alluvium, Jackson Formation(?), and the Claiborne Group. The loess occurs only in the uplands east of Reelfoot Lake. In the valley, the alluvium occurs at land surface.

## WELL CONSTRUCTION

Twenty-three wells were installed using a hollow-stem auger drilling rig. Casing and screen were generally installed through the augers. After drilling, the augers were withdrawn and the formation material allowed to collapse around the screen and casing. The remaining annulus was backfilled with cuttings and then grouted at land surface. All wells were constructed with PVC casing and a 0.020-inch slot screen. At each site, one 4-inch diameter well was installed approximately 30 to 35 feet below land surface. Two-inch diameter observation wells were also installed to approximately the same depth at three sites to be used during aquifer tests. At three of the sites, deeper wells were

installed (60 and 100 feet below land surface) to provide information on vertical hydraulic gradients. Well-construction data are listed in table 1 and construction diagrams are included in Appendix A.

## GEOLOGY

Geologic samples were collected at 5-foot intervals during well construction and were used to determine the lithology of the formations. A log of the samples was kept for each well and was compared with gamma logs made at each site. The lithologic and gamma log for each site is presented in Appendix A.

Three principal lithologies were encountered in different areas around Reelfoot Lake. Near the southwest corner of the lake, at well site 55, approximately 40 feet of tight, brown to brown-gray clay and silty clay occurred below land surface. The clay was underlain by at least 15 feet of sand and silty sand. In this area, deep, possibly clay-filled meanders of the Mississippi River have been mapped previously (Stearns, 1981).

Near the northwest corner of Reelfoot Lake, at well sites 44 through 48, 53, and 54, approximately 10 to 20 feet of surficial silt and clay was encountered. Medium- to coarse-grained sand and some gravel occurred below the surficial sediments. The sand and gravel was up to 70 feet thick at well 46C. Well sites 49 through 52, near Pond

<sup>1</sup> Altitude determined from topographic map.

Slough and Lake No. 9, were underlain by 20 to 30 feet of silt and silty clay. This was underlain by very-fine to fine sand interbedded with silt and silty sand. Fine- to coarse-grained sand occurred below this zone to about 100 feet below land surface at well site 51.

140 gal/min (table 2). Specific capacities in the alluvial aquifer ranged from less than 1 gallon per minute per foot of drawdown (gal/min/ft) to 17.1 gal/min/ft at well 51B. All tests were conducted with a centrifugal pump or a 4-inch submersible pump, and discharge was monitored during the test.

## SPECIFIC-CAPACITY TESTS

The observation wells were pumped to determine yields and the specific capacity of the alluvial aquifer. Yields ranged from about 1 gallon per minute (gal/min) to about

## WATER QUALITY

Water-quality samples were collected at six wells during February 1987. The samples were analyzed for

major constituents, trace metals, and nutrients (table 3). Wells 44A, 46A, 53A, and 54 are completed in the upper 30 feet of the alluvial aquifer and provide representative samples for that interval. Samples from wells 53B and 53C along with the sample from well 53A were collected to provide information on vertical changes in water quality within the alluvium.

Specific conductance in the upper 30 feet of the alluvium ranged from 225 microsiemens per centimeter at well 44A to 750 microsiemens per centimeter at well 54. Dissolved nitrite and nitrate was highest, 4.4 milligrams per liter as nitrogen, at well 44A. Water-quality samples at site 54 showed little variation in water quality with depth. Specific conductance was 430, 430, and 425 microsiemens per centimeter at wells 53A, 53B, and 53C, respectively (table 3).
