LATEST MESOZOIC AND CENOZOIC IGNEOUS ROCKS
OF SOUTHEASTERN ALASKA--A SYNOPSIS
By
David A. Brew

INTRODUCTION

The most important latest Mesozoic and Cenozoic, post-accretionary
dislocations of southeastern Alaska are the magmatic activity that
affected a large part of the region and the metamorphism and deformation that
was interspersed with that activity. This report is a preliminary version of
a report on this magmatism prepared for the Decade of North American Geology
(DNAG) volume on Alaska. The magmatic activity is a continuation of the late
Mesozoic igneous events that will be discussed in the DNAG volume by T.P.
Miller. The metamorphic history will be discussed in the DNAG volume by C.
Dusel-Bacon.

The post-accretionary geologic history starts with the accumulation of
the Gravina belt overlap assemblage of rocks in Late Jurassic and Early
Cretaceous time (Berg and others, 1972). The locally voluminous volcanic
rocks within that assemblage are probably the extrusive equivalents of island-
arc intrusive rocks that are preserved west of the Gravina belt over a large
area in northern southeastern Alaska (Brew and Morrell, 1983). Neither those
volcanics nor granitoids are discussed in this paper.

Previous syntheses concerned with the magmatic rocks of southeastern
Alaska comprise a summary of post-Carboniferous volcanic activity (Brew,
1968), summaries of the distribution and general characteristics of the
plutonic rocks (Brew and Morrell, 1980, 1983), a summary of the geochronologic
data available (Wilson and Shew, 1982), and two reports concerned with the
tectonic significance of major and trace element chemical data (Barker and
Arth, 1984; Barker and others, 1986). Karl and Brew (1984) discussed
migmatitic rocks associated with some of the intrusive rocks; that topic is
not considered in this report. This present report summarizes a more lengthy
and complete study on this same topic that is in preparation.

In this report, the latest Mesozoic and Cenozoic plutonic and volcanic
rocks are grouped chronometrically; the same time divisions are to be used in
the DNAG volume for the Cenozoic magmatic history of the remainder of Alaska by
E. Moll-Stalcup. The divisions are approximate, and several of the belts
described in the region include rocks whose radiometric ages fall somewhat
outside of the defined limits. Within each chronometric group, extrusive and
intrusive rocks are identified compositionally and are separated into
geographic belts. The general approach is similar to that of Brew and Morrell
(1983). Table 2 provides summary information on modal and chemical
compositions, chronometric data, and emplacement/eruptive environment for each
of the chronometric groups. The chemical classifications of the rocks are
those of Shand (1951) and Irvine and Baragar (1971). Figure 1 shows the
general geographic distribution of the rocks of different ages and is an index
map for the descriptions in the table.

Igneous activity in southeastern Alaska ranges from early Paleozoic to
Holocene in age but was most frequent in the late Mesozoic and Cenozoic.
Currently available geochronologic data for southeastern Alaska are summarized
in Figure 2, which shows the frequency distribution for 402 age determinations
of all types of rocks from southeastern Alaska southeast of the Yakutat
1:250,000 scale quadrangle. The relative recency of magmatic activity in the
region is obvious, as are the dominance of mid-Tertiary events and the absence
of any real break between Mesozoic and Cenozoic events.

DESCRIPTION OF THE TABLES

Table 1 links the major magmatic belts and areas of summary discussions
in the text and of Figure 3 with the descriptions of the component belts and
areas given in Table 2. The information presented in Tables 1 and 2 is
derived from Brew (in press); that report contains more discussion of tectonic
settings, emplacement situations, and extrusive activity than can be included
here. Table 2 summarizes the data that support the conclusions of this
report. However, the many intermediate inferences that relate the data to the
conclusions are still unpublished.

Table 2 is divided into columns for: (1) Figure 1 reference, which is
the letter designation on those maps for the specific area; (2) Area or belt
name; (3) Major and minor lithic types, with the latter shown in parentheses,
granitic rock names are from Streckeisen (1973); (4) Chemical classification
and chemical compositional types present, based on calculations using the
PETCAL 4 program (Bingler and others, 1976) as revised by R.D. Koch (written
commun., 1985)); (5) SiO₂ range; (6) SiO₂ gap(s); (7) Reference to map and
diagram figures in this report; most figures include a Streckeisen (1973) QAP
(quartz-alkali feldspar-plagioclase feldspar) classification diagram for
granitic rocks, a silica-variation diagram, an AFM (alkaline element oxide-
iron oxide-magnesium oxide) diagram, and a small map showing the area
containing the rocks described; (8) Age data; (9) Discussion or remarks,
focussed mainly on the environment-of pluton emplacement or volcanic
extrusion; and (10) References to the sources of the data.

EVOLUTION OF MAGMATIC BELTS AND AREAS

The tectonic settings and compositional variations recorded in the
several Cenozoic magmatic belts of southeastern Alaska indicate that the belts
have had a varied and complicated evolutionary history. The older part of the
record, from latest Cretaceous through about early Oligocene time, reflects
the two main collisional events that dominate the Cenozoic history of the
region. The younger part of the record, from the late Oligocene on, is the
result of less well understood events, ones that are probably related first to
oblique subduction and then to extensional regimes associated with youngest
Cenozoic strike-slip faulting.

The areas summarized in Tables 1 and 2 are grouped into nine major belts
on Figure 3: the "great tonalite sill" belt is of latest Cretaceous and
Paleocene age (75-55 Ma); the Coast Mountains belt is of early and middle
Eocene age (55-45 Ma); the Fairweather-Baranof and Glacier Bay region belts
are of middle and late Eocene and early Oligocene age (45-35 Ma), the Tkope-
Portland Peninsula, Groundhog Basin-Cone Mountain, and southern southeastern
Alaska dike swarm belts are of late Oligocene and Miocene age (35-5 Ma); and
the Kruzof-Kupreanof and Behm Canal-Rudyerd Bay areas are of Pliocene and
Quaternary age (5-0 Ma). Each of these belts is interpreted to record a
specific magma-generating event (or series of events) and most have clear-cut
chemical and(or) modal compositional features that support the definition of the belts.

GREAT TONALITE SILL BELT

The oldest belt discussed here, the latest Cretaceous and Paleocene "great tonalite sill" belt (Skagway/Ketchikan-PrinceRupert (75-55 Ma) on Figure 3 and Tables 1 and 2), records only the youngest of a series of events that began in Early Cretaceous time in the "southeastern Alaska coincident zone" (Brew and Ford, 1985). Earlier volcanic and plutonic history will be discussed by T.P. Miller in the DNAG volume. The rocks of the tonalite sill belt are consistently calcalkalic and dominantly metaluminous, locally have a prominent silica gap at 63 to 68 percent, and fall in the tonalite-granodiorite-quartz monzodiorite-quartz diorite fields of Streckeisen (1973). These plutons have emplacement ages that range from 67 to 55 Ma. The sill rocks with Paleocene emplacement ages of around 60 Ma are included with the older tonalite sill family because of their closely similar ages and habits. They are mostly granodiorite and have higher silica contents than the slightly older rocks.

The plutons of the great tonalite sill belt are foliated and lineated tonalites that form a narrow belt that is over 900 km long and only 5 to 30 km wide. They have been localized along a profound, straight, linear structural discontinuity within a convergent setting in which the northeast side was moving upwards relatively over the southwest side (D.H.W. Hutton, oral communis., 1985, 1986). This discontinuity can be interpreted as either a within-plate rift margin (Brew and Ford, 1983) or as the boundary between two exotic terranes (Monger and others, 1982, 1983). The linear zone of compression persisted at least from 70 Ma to 55 Ma, the tonalite period during which intrusions were emplaced. Metamorphism and major deformation occurred shortly before the emplacement of the intrusions.

The cause of the compression in this zone, whether it was originally a rift or an ocean between two different terranes, was the movement of the outboard Alexander terrane towards the northeast (Monger and others, 1982). This movement is interpreted to have preceded the convergence of the Chugach terrane against the westward margin of the Alexander terrane (Plafker and others, 1977; Johnson and Karl, 1985). The consistent composition of the magmas argues for a deep and equilibrated source, even though the preliminary data of Arth and others (1986) on strontium initial ratios indicate possible derivation from continental source materials. This latter possibility can be used to support a within-plate-rift origin of the structural discontinuity that localized the tonalite sill belt and the other nearby parallel features of the southeastern Alaska coincident zone (Brew and Ford, 1985).

COAST MOUNTAINS BELT

The linear Coast Mountains belt along the International Boundary (Skagway/Ketchikan-Prince Rupert Coast Mountains belt (55-45 Ma) on Figure 3 and Tables 1 and 2) is over 1,000 km long and up to 90 km wide and consists of a large volume of early and middle Eocene plutons that are probably a result of the convergence and crustal thickening associated with the compressive event just described. These rocks are consistently calcalkalic, dominantly metaluminous north of the Sumdum area, and exclusively moderately peraluminous
to the south. The overall range in silica content is 53 to 76 percent; the average silica content is about 67 percent to the north of the Sumdum area and 72 percent to the south. Modally, the rocks are dominantly sphene-hornblende-biotite granodiorite, granite, and tonalite. Available age determinations indicate that the plutons in the southern part of the Coast Mountains were emplaced between 55 and 45 Ma and those in the northern part from 54 to 49 Ma. The Coast Mountains belt of large composite plutons parallels the great tonalite sill belt, commonly within a few kilometers and in several places intrudes that belt.

The differences in age, structural habit, and composition of the rocks in this belt indicate a different origin from that of the great tonalite sill belt. The general absence of all structures but flow foliation, and the restricted thermal aureoles that are superposed on the earlier Barrovian-type metamorphism associated with the tonalite sill belt, indicate that these early and middle Eocene intrusions are post-tectonic and their emplacement followed the abrupt uplift that accompanied and closely followed intrusion of the sill belt.

The composition of the plutons in the Coast Mountains belt, their location in relation to the highly deformed and presumably thickened crust near the tonalite sill belt, and the time-lag relations all indicate that the Coast Mountains belt is the result of the thickening that occurred during the latest Cretaceous and early Tertiary collision discussed above. The change from metaluminous to moderately peraluminous composition from north to south is inferred to be related to the type of material conveyed to depth in the convergent zone. This may be a result of the greater thickness of older continental crust in the southern part of the Alexander terrane compared with the northern part.

**FAIRWEATHER-BARANOF BELT**

Plutons of the Fairweather-Baranof belt and the Glacier Bay region (Fig. 3, Tables 1 and 2) were emplaced in the time span of late Eocene to early Oligocene (45-35 Ma). The Fairweather-Baranof belt is about 350 km long by 50 km wide and is parallel to the Coast Mountains belt approximately 200 km to its southwest. Emplacement ages of 49 to 39 Ma indicate that the Fairweather-Baranof belt is definitely younger than the Coast Mountains belt, although there is some overlap. Biotite-hornblende tonalite and granodiorite are the most common rock types in the southern part of the Fairweather-Baranof belt, and gabbro-norite, pyroxenite, and other mafic and ultramafic rocks dominate the northern part. The granitic plutons are calcalkalic, mostly peraluminous, and have silica contents that range from 60 to 73 percent. The belt occurs largely within the Chugach terrane and is interpreted to have formed as a result of the convergence and accretion of the Chugach terrane. Metamorphic mineral ages suggest that the convergence occurred in Late Cretaceous time, though before the time of the main deformation and metamorphism associated with the great tonalite sill belt.

In this interpretation, the Coast Mountains and the Fairweather-Baranof belts are not quite synchronous and are not directly related; either could have formed independently. The Coast Mountains belt is one result of the closure of the Gravina basin because of northeastward movement of the Alexander terrane, whereas the Fairweather-Baranof belt is one result of the
accretion of the Chugach terrane to the west side of the Alexander terrane.

GLACIER BAY REGION

The Glacier Bay region (Fig. 3, Tables 1 and 2) is, in contrast to the magmatic belts described, a northeast-trending, nearly rectangular 80 km by 70 km area that slightly overlaps the northern part of the Fairweather-Baranof belt geographically and also in time, with ages ranging from about 42 to 30 Ma. The calcalkalic plutons are dominantly unfoliated to poorly foliated, metaluminous and moderately peraluminous biotite granite and alkali granite. Silica values range from 58 to 76 percent. This group of plutons is areally, compositionally, chemically, and structurally distinct from those in the Fairweather-Baranof belt, and their origin, although linked to the latter, must differ in some significant way. One possibility is that the plutons of the Glacier Bay region represent the silicic remnant of a magmatic system that produced the dominantly gabbroic plutons in the adjacent northern part of the Fairweather-Baranof belt, and that the emplacement of the silicic portion was displaced to the northeast by the previously emplaced less fractionated mafic and ultramafic bodies. Another possibility is that they are an early manifestation of the younger (35-5 Ma) Tkope-Portland Peninsula belt (discussed below), which is related to some obscure regime that occurred after Chugach-terrane accretion and before transform faulting.

TKOPE-PORTLAND PENINSULA BELT

The Tkope-Portland Peninsula belt, the Groundhog Basin-Cone Mountain area, and the southern southeastern Alaska dike swarm (Fig. 3, Tables 1 and 2) were emplaced within the time span of and late Oligocene and Miocene (35-5 Ma). The three belts are clearly different from the collision-related belts just described; each has distinct petrological characteristics and represents different types of magma-generating events.

The Tkope-Portland Peninsula belt (Fig. 3, Tables 1 and 2) is the most prominent of the three belts or areas. It extends in a northwest-southeast direction for at least 560 km across all of southeastern Alaska, cutting across all tectonostratigraphic terranes, except the Chugach at an angle of about 15°. Both volcanic and plutonic rocks occur in the belt. The volcanic rocks are flows, tuff, and breccia of andesitic, basaltic, rhyolitic, and dacitic composition. All are calcalkalic, and silica contents range from 47 to 77 percent with a significant gap at 61 to 66 percent. Available age determinations indicate that the volcanics were erupted during the period from about 25 to 16 Ma. The granitics are both calcalkalic and alkalic. Granite and granite porphyry are the most common rock types at the ends of the belt; most are moderately peraluminous. Alkali granite, granite, quartz syenite, and alkali quartz syenite are common types in the central part. Leucogabbro and gabbro occur locally. The plutonic rocks have a silica range of 49 to 77 percent with significant gaps at 54 to 56 and at 61 to 65 percent. The plutons were emplaced from 35 to 19 Ma, with those at the northwest ends of the belt about 28 to 24 Ma, those in the center at 24 to 19 Ma, and those at the southeast end at 30 Ma and 27 to 24 Ma.

The length and continuity of the Tkope-Portland Peninsula belt suggest that it could be the result of a significant collisional event of unusual orientation. However, no other evidence supporting such an origin has been
preserved, and thus it is considered unlikely. The composition of the plutons is unlike those in the other magmatic belts, probably because the magmas were generated at the base of or within the continental crust of the Alexander/Stikine terranes. The cause of the magmatic events is probably related to the change from convergence to oblique subduction to strike-slip movement between the Pacific and North American plates, but the actual mechanism that caused the long belt to form is not clear. The axis of the belt coincides with the orientation of the tension planes that would be associated with the onset of differential strike-slip movement along the continental margin. The slight change in orientation of the belt near its southeast end could be related to differences in the thickness of the crust.

GROUNDHOG BASIN-CONE MOUNTAIN AREA

The Groundhog Basin-Cone Mountain area includes rhyolitic sills and biotite granite plugs in an area 10 km by 40 km (Fig. 3, Tables 1 and 2). Alkali granites may be present in the Cone Mountain area, but available data indicate that the rocks are calcalkalic and moderately peraluminous and have a silica content from 74 to 76 percent. The granites were intruded at about 16 Ma, definitely later than the rocks in the Tkope-Portland Peninsula belt. The plutons were intruded at a high crustal level under static conditions, but their relations to other belts and to possible localizing factors are obscure.

SOUTHERN SOUTHEASTERN ALASKA DIKE SWARM

The southern southeastern Alaska dike swarm (Fig. 3, Tables 1 and 2) consists mostly of lamprophyres that occupy a significant part of a northeast-trending belt about 100 km wide and greater than 150 km long. Granitic and volcanic rocks are also present. The swarm overlaps the southeastern end of the Tkope-Portland Peninsula belt, and at least some of the dikes are closely related to the plutons there. The lamprophyres are alkalic, and most are classified as alkali-olivine rocks. The non-lamprophyres are calcalkalic and have a silica content ranging from 56 to 71 percent.

The age of intrusion of the lamprophyres is not well known; they cut plutons with ages of 27-24 Ma in the Tkope-Portland Peninsula belt but are not known to cut the plutons of the Groundhog Basin area with ages of 17-14 Ma. Souther (1970) interprets them as the deeper expression of the dated Miocene alkalic volcanic fields to the northeast in British Columbia. Those fields are inferred to be localized in belts of large-scale crustal extension related to continental-margin transect faulting; the dikes follow joints that are perpendicular to the foliation and resulted from the relaxation of the major stresses that affected the Coast crystalline belt in earlier Tertiary time.

KRUZOF-KUPREANOF AND BEHM CANAL-RUDYERD BAY AREAS

Two areas or belts of Pliocene and Quaternary volcanic rocks are shown on Figure 3 and described in Tables 1 and 2. The first, the Kruzof-Kupreanof area of Holocene rocks, appears as two segments separated at the Chatham Strait fault because it postdates the major offset that was removed in constructing the palinspastic base for the figure. This area consists of two widely spaced volcanic fields of similar age and chemical composition. Those fields, Edgucumbe and southern Kupreanof, contain tholeiitic basalt, and the Edgucumbe field also has calcalkalic younger flows and pyroclastic rocks.
Most, but not all, of the flows are interpreted to be postglacial. Together the two fields define an east-west-trending area similar in orientation to the east-west Holocene volcanic belts in the west-central British Columbia region; Souther (1970) relates the localization of the latter belts to large-scale crustal extension.

The second area of Pliocene and Quaternary volcanic rocks is the Behm Canal-Rudyerd Bay volcanic field, most of which occurs within the area covered by the southern southeastern Alaska dike swarm. The small Blue River-Unuk River volcanic field to the north (Fig. 1) is considered an outlier of the Behm Canal-Rudyerd Bay field. Both fields contain alkali olivine basalts and other alkalic rocks that are somewhat similar to the alkali to peralkaline basalts in the Mount Edziza field, which is located about 100 km to the north in Canada. Souther and Armstrong (1966), Souther (1970), and Souther and others (1984) relate the north-south orientation of the Mount Edziza field to large-scale crustal extension. It is likely that this area is an outlier of that large field.

SUMMARY

The Cenozoic volcanic and plutonic rocks of southeastern Alaska record a progression of events that are related to the tectonics of the northeastern Pacific margin. The progression started with the collisional/convergent events related to the accretion of the Alexander terrane to the "Stikine" terrane; the progression continued with the events related to the accretion and subduction of the Chugach terrane on the west side of the Alexander. These events along the northeastern Pacific margin occurred in late Cretaceous and early Tertiary time; they were followed by events related first to oblique subduction and then to transition to dominantly transcurrent movements. The progression ended with magmatic events localized along extensional zones that may be related either to present-day right-lateral crustal displacements in the northeastern Pacific region or to residual stresses that originated in the late stages of convergence. Figure 24 summarizes these time and space relations.

| **N** Kuiu-Etolin volcanic-plutonic belt | Basalt and andesite flows; rhyolite flows and tuffs, vent and other breccias; alkali granite, granite, quartz syenite, (gabbro) | Volcanics (volcanics) mostly tholeiitic per MacDonald and Katsura (1964) and Miyashiro (1974), but calcalkaline, aver. and low K-content per Irvine and Baragar (1971). Granitics are mostly peraluminous and metaluminous, calc-alkaline, K-poor or K-aver., and only a few are peralkaline or alkalic | Volcanics (granitoids) mostly tholeiitic per MacDonald and Katsura (1964) and Miyashiro (1974), but calcalkaline, aver. and low K-content per Irvine and Baragar (1971). Granitics are mostly peraluminous and metaluminous, calc-alkaline, K-poor or K-aver., and only a few are peralkaline or alkalic | 46-76 | 61-65 | 8, 9, 10 | Volcanics 22-20 Maa on whole-rock K-Ar; granitoids 19-24 Ma (Douglass and Katsura, 1987) | Heterogeneous volcanic and plutonic complex; 1979, 1984; Hunt, 1984; Douglass and others, 1988;
Heterogeneous volcanic and plutonic complex; 1979, 1984; Hunt, 1984; Douglass and others, 1988; R.P. Morrell, written commun., 1986 |

| **O** Groundhog Basin area | Rhyolite, biotite granite | Peraluminous per Shand (1951); tholeiitic per Mac Donald and Katsura (1964), but calcalkaline, K-poor per Irvine and Baragar (1971) | (volcanics) mostly tholeiitic per MacDonald and Katsura (1964) and Miyashiro (1974), but calcalkaline, aver. and low K-content per Irvine and Baragar (1971). Granitics are mostly peraluminous and metaluminous, calc-alkaline, K-poor or K-aver., and only a few are peralkaline or alkalic | 74-76 | (granitoids) mostly tholeiitic per MacDonald and Katsura (1964) and Miyashiro (1974), but calcalkaline, aver. and low K-content per Irvine and Baragar (1971). Granitics are mostly peraluminous and metaluminous, calc-alkaline, K-poor or K-aver., and only a few are peralkaline or alkalic | 10 | Sill 15 Ma on whole-rock K-Ar; plug 16 Ma on biotite K-Ar | Prominent rhyolite sill swarm apparently centered on granitic or felsic volcanic plugs | Brew and others, 1984; Douglass and others, 1988; R.P. Morrell, written commun., 1986 |

| **P** Southern Etolin field | Basalt flows, andesite breccias | No data | No data | No data | N.A. | No data | May be outlier of Kuiu-Etolin volcanics | Berg and others, 1976; Eberlein and others, 1983 |

| **Q** East-central Prince of Wales field | Basalt and rhyolite breccia and tuff | No data | No data | No data | N.A. | No data | Very poorly known small isolated occurrences | Eberlein and others, 1983 |

| **R** Suemez field | Olivine basalt flows, basalt breccia, lapilli tuff, rhyolite and dacite flows | Peraluminous (granitoids) per Irvine and Baragar (1971); tholeiitic per MacDonald and Katsura (1964) | Peraluminous (granitoids) per Irvine and Baragar (1971); tholeiitic per MacDonald and Katsura (1964) | 72 | N.A. | N.A. | Associated with Tertiary (?) coal seams | Poorly known field, may be closely related to Tlevak field (D) | Eberlein and others, 1983; G.D. Eberlein, written commun., 1986 |

ILLUSTRATIONS

FIGURE 1. Cenozoic plutonic and volcanic rock localities in southeastern Alaska. Letters refer to areas described in Tables 1 and(or) 2. Lined pattern indicates approximate extent of areas; boundaries between contiguous areas of the same age are omitted. Lines labelled "W" are the northwest and southeast boundaries of the southern southeastern Alaska dike swarm.

FIGURE 2. Histogram showing distribution of radiometric ages for southeastern Alaska.

FIGURE 3. Latest Mesozoic and Cenozoic magmatic belts, fields, and areas in southeastern Alaska; ages given in parentheses are those from the organization of the text and table and do not in every case reflect the full range of ages of the rocks in the belts. One-hundred and twenty kilometers of right-lateral separation on the Lynn Canal-Chatham Strait fault has been removed. Different line types are used only to clarify relations between overlapping belts.

FIGURE 4: Composite diagrams for rocks of Holocene age from the Edgecumbe volcanic field (location shown on fig. 5). A, AFM diagram after Irvine and Baragar (1971), non-tephra-deposit samples, data from J.R. Riehle (written commun., 1986); B, silica-variation diagram, non-tephra-deposit samples, data from Brew and others (1969), Myers and Marsh (1981), and Kosco (1981); C, AFM diagram, tephra-deposit samples, data from J.R. Riehle (written commun., 1986); D, silica-variation diagram, tephra-deposit samples, data from Riehle and Brew (1984).

FIGURE 5. Location map and composition diagrams for rocks of Holocene age from A, the southern Kupreanof volcanic field (B), Blue River-Unuk River volcanic field (C), Tlevak Strait field and (D) Behm Canal-Rudyerd Bay volcanic fields (E). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram. Data sources: Douglass and others (1988), R.L. Elliott (written commun., 1986), Wanek and Callahan (1971), and Ouderkirk (1982).

FIGURE 6. Location map and composition diagrams for rocks of late Oligocene and Miocene age from A, the Icy Strait belt (K) and the Admiralty Island volcanic field (M). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram. Data sources: D.A. Brew (unpub. data, 1985); Loney (1964), G. Plafker (written commun., 1986).

FIGURE 7. Chondrite-normalized rare-earth-element diagram for rocks of late Oligocene and Miocene age from the Icy Strait belt (dots) and Admiralty Island volcanic field (circles). Data from D.A. Brew (unpub. data, 1985) and G. Plafker (written commun., 1986).

FIGURE 8. Location map and composition diagrams for volcanic rocks of late Oligocene and Miocene age from A, the Kuiu-Etolin volcanic-plutonic belt (N). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram. Data source: Douglass and others (1988).

FIGURE 9. Chondrite-normalized rare-earth-element diagrams for rocks of late
Oligocene and Miocene age from the Kuiu-Etolin volcanic-plutonic belt. A, Basalts and andesites; B, Rhyolites (dots) and granitic rocks (circles). Data source: D.A. Brew (unpub. data, 1985).

FIGURE 10. Location map and composition diagrams for plutonic rocks of late Oligocene and Miocene age from A, the Kuiu-Etolin volcanic-plutonic belt (N) and Groundhog Basin area (O). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzodiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; AM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: Douglass and others (1988), and Hunt (1984).

FIGURE 11. Location map and composition diagrams for plutonic rocks of late Oligocene and Miocene age from A, the Quartz Hill/Portland Peninsula area (V). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzodiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: Smith and others (1977); Hudson and others (1979).

FIGURE 12. Location map and composition diagrams for granitic and gabbroic rocks of Miocene and late Eocene and early Oligocene age from A, the Glacier Bay region (X) and the Yakobi, Chichagof, and Baranof area (Z). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzodiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: Himmelberg and Loney (1987), and Brew (unpub. data) for all but Baranof area; Wanek and Callahan (1969) and Callahan (1978) for Baranof area.

FIGURE 14. Location map and composition diagrams for granitic rocks of early and middle Eocene age from A, the Haines-Skagway area (AA). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzodiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite; FeO* indicates total Fe as FeO. Data source: Barker and others (1986).

FIGURE 16. Location map and composition diagrams for granitic rocks of early and middle Eocene age from A, the Juneau-Taku River area (BB). B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data source: D.A. Brew and A.B. Ford (unpub. data, 1985).

FIGURE 17. Location map and composition diagrams for granitic rocks of early and middle Eocene age from A, the Sumdum (CC) and Petersburg (DD) areas. B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: D.A. Brew and A.B. Ford (unpub. data, 1985) for Sumdum; Douglass and others (1988) for Petersburg.

FIGURE 19. Location map and composition diagrams for granitic rocks of early and middle Eocene age from A, Bradfield Canal (EE) and Ketchikan (FF) areas. B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, Tonalite. Data sources: Webster (1984) and Smith (1977) for Bradfield Canal area; Smith (1977) for Ketchikan-Prince Rupert area.

FIGURE 20. Location map and composition diagrams for granitic rocks of Paleocene age from A, the Juneau-Skagway area (GG). B, AFM diagram (Irvine and Baragar (1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data source: D.A. Brew and A.B. Ford (unpub. data, 1985).
FIGURE 21. Location map and composition diagrams for granitic rocks of latest Cretaceous age from A, the Haines-Skagway (HH) and Juneau-Taku River (II) areas. B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: D.A. Brew and A.B. Ford (unpub. data, 1985) and Barker and others (1986).

FIGURE 23. Location map and composition diagrams from granitic rocks of latest Cretaceous age from A, the Sumdum (JJ), Petersburg (KK), and Ketchikan-Prince Rupert (MM) areas. B, AFM diagram (Irvine and Baragar, 1971); C, Silica-variation diagram; D, general plutonic rock classification diagram (Streckeisen, 1973): AF, alkali-feldspar granite; AQ, alkali-feldspar quartz syenite; AS, alkali-feldspar syenite; DI, diorite; GR, granite; GD, granodiorite; MD, monzondiorite; MO, monzonite; QD, quartz diorite; QO, quartz monzodiorite; QM, quartz monzonite; QS, quartz syenite; SY, syenite; TO, tonalite. Data sources: D.A. Brew and A.B. Ford (unpub. data, 1985) and Brew and Grybeck (1984) for Sumdum; Douglass and others (1988) for Petersburg; and Smith (1977) for Ketchikan-Prince Rupert.

FIGURE 24. Time space diagram summarizing latest Mesozoic and Cenozoic magmatism in southeastern Alaska.

TABLES

TABLE 1. Major latest Mesozoic and Cenozoic magmatic belts and areas of southeastern Alaska.

TABLE 2. Description of latest Mesozoic and Cenozoic magmatic rocks of southeastern Alaska. See text for discussion.
FIGURE 2.
FIGURE 4.
EXPLANATION
Rocks of Holocene age from
- Southern Kupreanof volcanic field
- Blue River-Unuk River volcanic field
- Behm Canal-Rudyerd Bay volcanic field
- Tlevak Strait volcanic field

FIGURE 5.
EXPLANATION
Rocks of late Oligocene and Miocene age from

- Icy Strait Belt
- Admiralty Island volcanic field

FIGURE 6.
FIGURE 7.

RARE-EARTH ELEMENTS

ROCK CHONDRITE
FIGURE 8.
FIGURE 9.
EXPLANATION
Plutonic rocks of late Oligocene and Miocene age from
- Kulu-Etolin belt
- Groundhog Basin area

FIGURE 10.
The image contains a map of a geographic region with the title "Yukon Territory - British Columbia". The region includes places like Juneau, Canada, United States, and others. The map is labeled with coordinates indicating locations and is scaled to show distances in kilometers. The map also includes a legend explaining the symbols used:

- **Quartz**
- **Alkali feldspar**
- **Plagioclase feldspar**

Below the map, there is an explanation in the text:

**EXPLANATION**

Rocks of middle and late Eocene and early Oligocene age from
- Glacier Bay region, granitic rocks
- Central Baranof area, granitic rocks
- Yakobi area, granitic rocks
- Yakobi area, gabbroic rocks

To the right of the map, there is a triangular graph labeled as:

- **F=FeO+0.8998 Fe₂O₃**
- **A=Na₂O+K₂O**
- **M=MgO**

This graph shows various points plotted on different axes, with labels for **FeO**, **TiO₂**, **Al₂O₃**, **P₂O₅**, **MgO**, **K₂O**, **CaO**, **Na₂O**, and a grid indicating weight percent of **SiO₂**.

At the bottom of the page, the text reads:

**FIGURE 12.**
EXPLANATION
- Granitic rocks
- Gabbroic rocks

FIGURE 13.
EXPLANATION

Samples from
  - The United States
  - Canada

FIGURE 14.
EXPLANATION

Samples from
- The United States
- Canada

FIGURE 15.
FIGURE 16.
EXPLANATION

Granitic rocks of early and middle Eocene age from

- Sumdum area
- Petersburg area
FIGURE 18.
EXPLANATION

Granitic rocks of early and middle Eocene age from

• Bradfield Canal area
• Ketchikan-Prince Rupert area

FIGURE 19.
FIGURE 20.
EXPLANATION

Granitic rocks of latest Cretaceous age from
- Juneau-Taku River area
- Haines-Skagway area

FIGURE 21.
