STUDIES RELATED TO AMRAP

The U.S. Geological Survey is required by the Alaska National Interests Lands Conservation Act (Public Law 96-487, 1980) to survey certain Federal lands to determine their mineral potential. Results from the Alaska Mineral Resource Assessment Program (AMRAP) must be made available to the public and submitted to the President and Congress. This report is one of a series of publications that presents geochemical and mineralogical results collected from the mineral assessment study of the Lime Hills 1:250,000 scale quadrangle, Alaska. The mineralogical data for nonmagnetic, heavy-mineral-concentrate samples from the eastern portion of the Lime Hills quadrangle are presented in this report.

INTRODUCTION

During the summers of 1987-88, a reconnaissance geochemical survey was conducted in the Lime Hills quadrangle, Alaska (fig. 1). The quadrangle is bounded by latitude 61° N to 62° N and by longitude 153° W to 156° W. The area comprises approximately 7,000 mi² (18,000 km²), although the area covered by this interim report represents only the eastern portion of the quadrangle (approx. 4,000 mi²; 10,000 km²) occupied by the Alaska Range and portions immediately adjacent. This report presents results of an ongoing reconnaissance survey, with completion expected in 1991. This interim report is deemed necessary due to the significance of the findings to be presented. In addition, the difference in geologic and physiographic character between the eastern portion of the quadrangle occupied by the Alaska Range and the western portion occupied by the lowlands of the Kuskokwim drainage basin warrant a separate interpretation of the data collected from each.

The portion of the quadrangle occupied by the Alaska Range is dominated by rugged, north-south trending ridges 4,000 to 7,000 ft (1,200 to 2,100 m) in elevation which rise abruptly from the lower terrain to the west. These ridges connect extremely rugged snowcapped peaks more than 9,000 ft (2,750 m) in elevation, the highest being Mount Hesperus (9,228 ft; 2813 m). Broad glaciated valleys with floors generally less than 3,000 ft (915 m) in elevation lie between the ridges. The western flank of the range consists of rolling hills and glacial pediments. Due to their mountainous topography, the Lyman Hills are also included in this report. Vegetation in the Alaska Range and on its flanks varies from barren mountain peaks to arctic tundra in glacial valleys, and northern latitude forest in lower valleys and lowlands west of the Alaska Range.

There is no road access to the Lime Hills quadrangle. The nearest reliable source of supplies is Anchorage, 130 mi (200 km) to the east. Only two sites of year-round habitation are located in the quadrangle, the Lime Village native settlement on the Stony River and the Sparrevohn U.S. Air Force Station in the southwest portion of the area. Improved airstrips capable of accommodating large, freight-hauling aircraft (e.g. C-130) are present at both of these sites. Unimproved airstrips and lakes that can accommodate small aircraft occur scattered throughout the quadrangle, though sites for landing in the Alaska Range are few. Approximately 14 percent of the quadrangle lies within the Lake Clark National Park and Preserve and is included in this study.

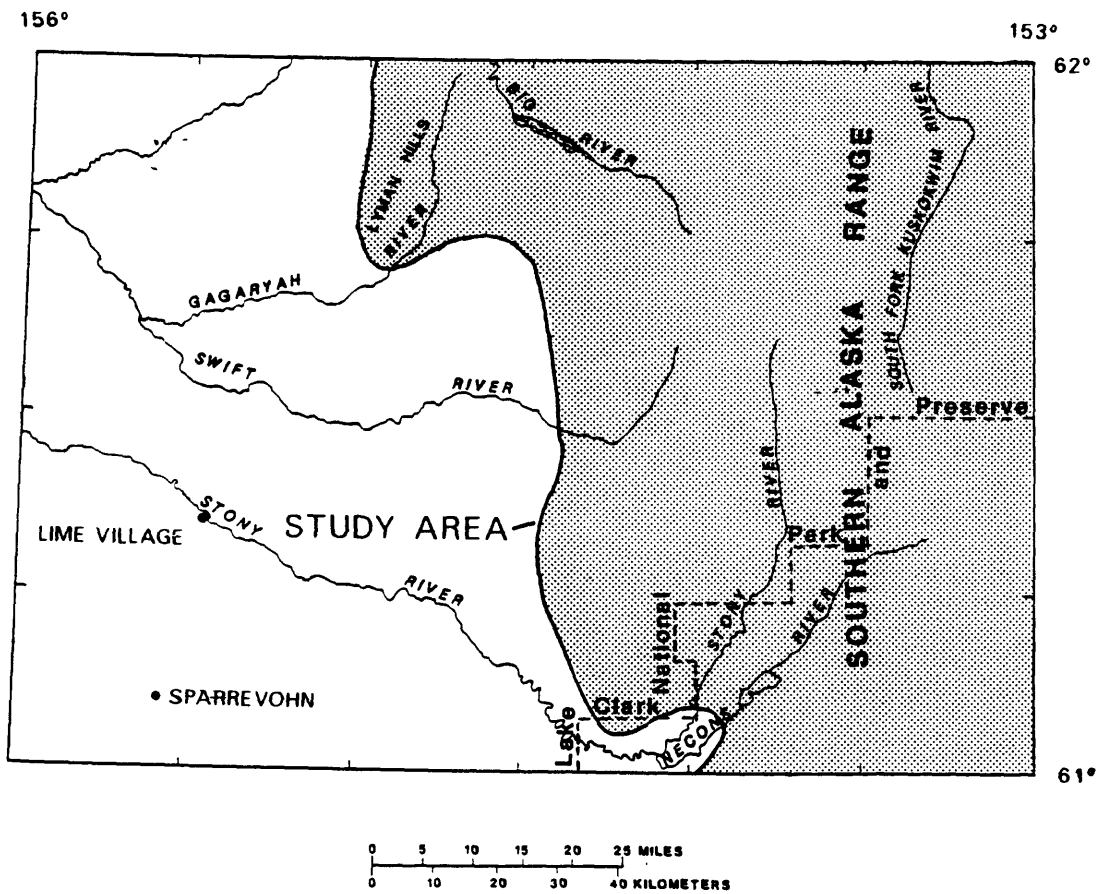

Figure 1. Index map of the Lime Hills quadrangle, Alaska

GENERAL GEOLOGY

Several major geologic features have been identified in the Lime Hills quadrangle including parts of the Dillinger, Nixon Fork, and Kahiltna lithotectonic terranes, the Kuskokwim Group sedimentary rocks and the Alaska-Aleutian batholith.

The Nixon Fork terrane (Jones and others, 1984) is a shallow-water carbonate platform and clastic sequence of Cambrian to Devonian age (Churkin, 1984; Blodgett and Clough, 1985). The Kuskokwim Group (Cady and others, 1955) is a sequence of deep to shallow marine, to non-marine clastic rocks of Early to Late Cretaceous age that unconformably overlie rocks of the Dillinger terrane. The rocks of the Nixon Fork terrane and Kuskokwim Group are present in the southwest portion of the quadrangle and are not included in the area covered by the present survey.

The Dillinger terrane, exposed in the northwest and north-central parts of the quadrangle consists of Cambrian through Devonian sedimentary rocks (Jones and others, 1984). The terrane is represented by a shallowing sequence of graptolitic shale, basinal carbonates, calcareous sandstones with minor chert and conglomerate, deposited in basinal, turbidite fan, and foreslope environments (Churkin, 1984; Bundtzen and others, 1987). The rocks of this terrane were isoclinally folded before the Jurassic period (Reed and Nelson, 1980).

The Kahiltna terrane (Jones and others, 1984) is an Upper Jurassic to Lower Cretaceous flysch sequence that consists dominantly of graywacke, phyllite and shale with local lenses of conglomerate. Minor limestone, radiolarian chert and ferruginous sandstone, siltstone and tuff are also present. The rocks of this terrane are strongly deformed and isoclinally folded.

The Alaska-Aleutian Range batholith includes rocks formed during three periods of igneous activity (Reed and Lanphere, 1973): a Middle to Late Jurassic period, a Late Cretaceous to early Tertiary period, and a middle Tertiary period. Jurassic plutonic rocks have not been identified in the Lime Hills quadrangle. Cretaceous to Tertiary plutonic rocks consist of an older group of quartz diorite to granodiorite plutons and a younger group of quartz monzonite to granite plutons. Middle tertiary igneous activity consists of quartz monzonite to granite plutons and intermediate to felsic volcanic flows, breccias, and tuffs.

The Denali fault system, a major northeast-trending, strike-slip fault system, occurs in the western portion of the quadrangle. On the Farewell segment of this system, 150 km of right-lateral movement has been interpreted (Blodgett and Clough, 1985). The Denali-Farewell fault system shows evidence of movement as late as Holocene time and may still be active (Bundtzen and others, 1986).

METHODS OF STUDY

Sample Media

Stream sediment is representative of rock material eroded from a drainage basin upstream from a sample site. Chemical analyses of stream sediment provide information which is useful in identifying basins which may contain concentrations of elements that may be related to mineral deposits. Whereas the composition of samples of bulk stream sediment is most reflective of lithologies exposed within a drainage basin, heavy-mineral concentrates of stream sediment

are selectively enriched in certain minerals, including many which may be ore-related. This concentration process permits direct microscopic observation of minerals that may be products of alteration or mineralization. With knowledge of ore deposit mineralogy, detrital mineralogical data may help place constraints on the permissible types of mineralization responsible for high levels of metals in the concentrate samples.

Sample Collection

The sampling for this survey included collection of stream-sediment and heavy-mineral-concentrate samples at most sites. This report concerns the 914 concentrate samples that were collected in the study area (plate 1). Geochemical data for stream-sediment samples is presented in Motooka and others (1989). Results of chemical analysis of heavy-mineral-concentrate samples are presented in Malcolm and others (1989). Geological and geochemical data for rock samples collected in the study area are presented in Allen and others (1989).

Sampling density for this drainage survey is about one sample per 4.5 mi^2 (11.6 km^2). The area of drainage basins sampled ranges from 1 to 10 mi^2 (2.6 to 26 km^2). Samples are composites of active alluvium collected primarily from first-order (unbranched) or second-order (below the junction of two first-order) streams as shown on the USGS topographic map of plate 1. In areas of active glaciation, samples were collected from major moraines selected as being representative of portions of the basin above.

Heavy-mineral concentrate samples were collected from bulk sediment which was initially sieved through a 10-mesh (2.0 mm) screen to remove coarse rock and vegetation fragments. Enough material was collected to fill a 16 in. diameter stainless-steel goldpan. A 1-2 lb (0.5-1 kg) bulk sediment sample was removed from the pan. The remaining material was panned until most quartz, feldspar, organic and clay-sized material was removed. The remaining material was packaged for additional laboratory preparation.

Sample Preparation

After drying, the heavy-mineral-concentrate samples were sieved through a 20-mesh (1mm) sieve. Bromoform (specific gravity = 2.85) was used to remove remaining low-density minerals from the concentrate samples. The resultant heavy-mineral sample was separated into three fractions using an electromagnet. The most magnetic fraction, consisting dominantly of magnetite and ilmenite, and the intermediate magnetic fraction, consisting dominantly of ferromagnesian silicates and oxides, were archived. The nonmagnetic fraction consists dominantly of heavy accessory minerals such as zircon, sphene, and apatite, but also contains most ore minerals, if present in a sample. These magnetic separates are the same that would be produced using a Frantz Isodynamic Separator set at a slope of 15 degrees and a tilt of 10 degrees with a current of 0.2 ampere to remove the most magnetic minerals and a current of 0.6 ampere to separate the intermediate and nonmagnetic fractions. The nonmagnetic fraction was split using a riffle splitter--one part for chemical analysis, and one part for mineralogical analysis.

Sample Analysis

Mineral identification was made using a binocular stereoscopic microscope. The most useful magnification ranged between 9X to 18X.

Identification was assisted through use of standard oil immersion methods using a petrographic microscope and through use of singlecrystal x-ray diffraction methods. Over 60 mineral species or rock-fragment types were observed in concentrates from the study area. Abbreviations of mineral names used in this report are listed in table 1. Estimates of the abundance of each mineral within each sample are presented in table 2.

DESCRIPTION OF DATA TABLE

Table 2 contains the mineralogical data for the nonmagnetic, heavy-mineral concentrate samples. The data are arranged such that the first column contains the USGS-assigned sample numbers. These numbers correspond to those shown on plate 1. Values given represent the abundance of a mineral relative to the total amount of nonmagnetic concentrate, except for gold, for which values are actual numbers of grains observed within a sample. Values listed in table 2 represent the following abundance ranges: 0 - mineral was not observed; 1 - trace to 1 percent; 2 - 1 to 2 percent; 3 - 2 to 10 percent, 4 - 10 to 25 percent; 5 - greater than 25 percent.

ACKNOWLEDGMENTS

We would like to acknowledge the following people for their assistance in the collection of samples for this study: E. Bailey, B. Cieutat, T. Delaney, K. Duttweiler, R. Golfarb, A. Hofstra, G. Lee, E. Leibold, S. Rose, and S. Smith. X-ray diffraction analyses were performed by S. Sutley.
