WATER-QUALITY AND WELL-CONSTRUCTION DATA FOR
SELECTED FARMSTEAD WELLS IN TENNESSEE

By Michael W. Bennett, John K. Carmichael, and Angel Román-Más

ABSTRACT

An investigation of the quality of ground water consumed by farmers in Tennessee was conducted in 1989 and 1990 by the U.S. Geological Survey, U.S. Department of the Interior, in cooperation with the Tennessee State Planning Office. Ground-water samples were collected from 150 wells representing varied hydrogeologic conditions and agricultural areas throughout the State. Analyses were made for physical characteristics, bacteria, major and trace inorganic constituents, nitrogen species, and total organic carbon. A nonquantitative, semiquantitative analytical scan was conducted for semivolatile organic compounds. Well-construction data were compiled from the University of Tennessee Agricultural Extension Service, the Division of Ground Water Protection of the Tennessee Department of Health and Environment, and landowners. A map showing the location of wells sampled was prepared and tables summarizing the results of the field and laboratory analyses were compiled. Well-construction and ground-water-level data were entered into the Ground-Water Site Inventory data base of the U.S. Geological Survey.

INTRODUCTION

Domestic wells supply the water demands of about one million people in Tennessee, including their drinking water needs (Hutson, 1988). Data on the quality of the water withdrawn from these wells are scarce. Until recently, no systematic monitoring programs were in place in the State to assess the quality of the ground water consumed by farmers and their families. Preliminary investigations conducted by the Tennessee Department of Health and Environment (TDHE) indicate that ground water in Tennessee is subject to potential contamination from natural and anthropogenic sources (Tennessee Department of Health and Environment, 1986).

In 1989, the U.S. Geological Survey (USGS), U.S. Department of the Interior, in cooperation with the Tennessee State Planning Office, initiated an investigation of the ground-water quality of selected farmstead wells in the State. A network of 150 wells was established, representing different hydrogeologic conditions and agricultural areas throughout the State. At each site, samples were collected for field and laboratory analyses of chemical, physical, and bacteriological characteristics. The field analyses included determinations of pH, specific conductance, water temperature, alkalinity, fecal coliform, and fecal streptococci bacteria.

Laboratory analyses were performed for principal anions and cations, trace inorganic constituents, dissolved solids, nutrients, and total organic carbon. A nonquantitative, semiquantitative scan for semivolatile organic compounds was conducted for each sample.

WELL SELECTION AND ACQUISITION OF CONSTRUCTION DATA

The following criteria were used to select wells included in the network and sampling:

- o Each well was a source of drinking water for the farmstead.
- o All wells were located on farms engaged in some type of agricultural activity at the time of sampling.
- o Documentation of past and present agricultural practices at the farm was available.
- o Data on the construction of the well were available.

The Agricultural Extension Service of the University of Tennessee (UTAES) assisted the USGS in the selection of the wells. The UTAES staff provided records for 562 candidate wells, including data on the hydrogeology of the site, agricultural practices, and construction data. Drillers' logs provided by the Division of Ground Water Protection of the TDHE, were used to supplement the UTAES records; 215 wells met the selection criteria indicated above. Further screening resulted in the selection of 150 wells as primary sampling sites, while the remaining 65 wells were identified as alternate sites. The owners of the prospective sampling wells were contacted to solicit their support to the project, confirm the UTAES and TDHE records, and to schedule the sampling. Alternate sites were selected after determinations were made that sampling at the primary site was not feasible. Every attempt was made to select an alternate site within the same county and aquifer, and with land use of the same category as the original site. The location of the final sites selected for the network are shown on plate 1.

SAMPLE COLLECTION

Water samples were collected after each well was purged. Stabilization of field measurements (temperature, specific conductance, and pH) was used as a criteria for purging. In general, purging of three to five casing volumes of water was needed before stabilization of field measurements was achieved.

Temperature, specific conductance, pH, and alkalinity were measured in the field following standard techniques of the USGS (Wood, 1981). The membrane filter method (Greenson and others, 1977) was used for bacteriological analysis (fecal coliform and fecal streptococci). Water samples for laboratory analysis were collected and preserved according to standard methods of the USGS (Wood, 1981; Pritt and Jones, 1989). The samples were analyzed at the National Water Quality Laboratory of the USGS in Arvada, Colorado. Techniques described by Fishman and Friedman (1989) and Wershaw and others (1987) were used for the laboratory analyses. Results of field and laboratory analyses were entered into the USGS's Water Data Storage and Retrieval System (WATSTORE).

DATA SUMMARY

Construction data, water levels, and identification of the principal aquifer tapped by each well are shown in table 1. Water-level measurements prior to purging of each well were obtained when feasible. The principal aquifer tapped by each well was defined using geologic maps and hydrogeologic descriptions by Bradley and Hollyday (1985).

Results of the water-quality analyses are shown in table 2. Several wells were re-sampled to confirm high values of selected water-quality characteristics, as part of the quality-assurance program of the Tennessee District of the USGS (Gaydos, 1983), or to replace samples lost in shipment.

Concentrations of total dissolved solids are reported as the total solid residue at 105 degrees Celsius. However, at sites 19, 27, and 47 (table 2), concentrations of total dissolved solids are reported as the sum of all major cations and anions. Total-nitrate concentrations were calculated by subtracting the total-nitrite concentration from the total nitrite plus nitrate concentration. Bacteriological analyses labeled as non-ideal count (K) implies that the number of bacteria colonies that developed on the filter was outside the ideal range, 20 to 60 and 20 to 100 colonies for fecal coliform and fecal streptococci, respectively.

Nonquantitative, semiquantitative analyses of organic compounds were performed using a scanning procedure based on gas chromatography with a flame-ionization detector (GC/FID). The GC/FID scanning method separates individual organic compounds. Although individual compounds are not identified, this scanning procedure is an economical means of determining which wells warrant more costly quantitative and qualitative analyses. Results of the GC/FID scans are reported in terms of the number of peaks identified, estimated total concentration, and the number of peaks possibly identified by gas chromatography/mass spectrometry.

Table 2.--Water-quality data for selected farmstead wells--Continued

[--, no data; <, less than; K, non-ideal colony count; *, computed value; μ S/cm, microsiemens per centimeter at 25 degrees Celsius; deg. C, degrees Celsius; cols./100 mL, colonies per 100 milliliters; mg/L, milligrams per liter; conc., concentration; wat wh tot it, water whole total incremental titration; GC/MS, gas chromatography/mass spectrometer; μ g/L, micrograms per liter]

| Site number | Alkalinity wat wh tot it field (mg/L as CaCO_3) | Sulfate dis-solved (mg/L as SO_4) | Chloride dis-solved (mg/L as Cl) | Fluoride dis-solved (mg/L as F) | Silica dis-solved (mg/L as SiO_2) | Solids residue at 105 deg. C, total (mg/L) | Iron, total recoverable (μ g/L as Fe) | Manganese, total recoverable (μ g/L as Mn) | GC/FID estimated total conc. (μ g/L) reported | GC/FID number of peaks identified by GC/MS | GC/FID number peaks poss. |
