ANNUAL PEAK DISCHARGES FROM SMALL DRAINAGE AREAS

IN MONTANA THROUGH SEPTEMBER 1989

by

J.A. Hull and R.J. Omang

ABSTRACT

Peak-streamflow data, collected since July 1, 1955, are presented in this report. Originally, 45 crest-stage gaging stations were established. Since 1955, the program of data collection has been expanded and reevaluated. As of the end of water year 1989, data were being collected at 158 stations and had been collected at 328 total stations. The stations record peak stages of flow from upstream drainage areas that range in size from less than 1 square mile to several hundred square miles. The purpose of the program is to collect sufficient peak-flow data to permit development of methods for estimating the magnitude and frequency of floods at any point in Montana.

For each station, this report briefly describes the station location, drainage area, period of record available, and type of gage including altitude of gage. The tabular data consist of annual maximum gage height and discharge listed by water year and month or month and day.

INTRODUCTION

Investigation of the magnitude and frequency of floods from small drainage areas in Montana was begun July 1, 1955. Originally, 45 crest-stage gaging stations were established. The program was expanded to 152 stations in 1959, and to 216 stations in 1963. The average number of stations operated was 214 from 1963 to 1967, 199 from 1968 through mid-1970, and 193 from mid-1970 through 1973.

An evaluation of the program in 1973 indicated that 62 existing stations needed to be continued for long-term record, all other stations could be discontinued on collection of 15 years of record, and about 100 new stations needed to be established to increase the station network density. During water years¹ 1974-75, 111 new stations were established, making a total of 328 sites at which data have been collected since 1955. During water year 1989, 158 gages were active--133 east of the Continental Divide and 25 west of the divide. The location of each active station is shown in figure 1.

The program of peak stage and discharge measurement is maintained by the U.S. Geological Survey. The program is conducted in cooperation with the Planning and Research Bureau of the Montana Department of Highways, and the Federal Highway Administration of the U.S. Department of Transportation.

This, the twenty-eighth report, presents, by water year, the annual maximum gage height (or stage) and the discharge at each active station. It also lists the annual maximum gage height and discharge at stations discontinued after September 1977 (shown in fig. 1). Records for stations discontinued prior to September 1977 are given in a report by Omang, Hull, and Parrett (1979).

¹A water year is the 12-month period October 1 through September 30. It is designated by the calendar year in which it ends.

PURPOSE OF THE PROGRAM

The purpose of the program is to collect sufficient peak-flow data to permit development of methods for estimating the magnitude and frequency of floods at any point in Montana. The ultimate objective is to determine methods for estimating the 1-percent-chance flood (one having a 100-year recurrence interval) with the reliability needed for road design. Reliability depends, in part, on having a relatively dense network of crest-stage gaging stations.

Part of the program has been fulfilled by a report of Boner and Omang (1967) based on data collected from 1955 through 1966. That report presents a method for determining the magnitude of floods having 10-year and 25-year recurrence intervals for drainage areas of less than 100 mi².

A second report (Johnson and Omang, 1976) gives methods for estimating magnitude and frequency of floods having recurrence intervals of as much as 100 years. This report does not meet the ultimate objective because the standard errors of estimate are large and the reliability is poor.

A third report (Parrett and Omang, 1981) gives revised techniques for estimating magnitude and frequency of floods having recurrence intervals of as much as 100 years. The estimating equations developed were a considerable improvement over the previous report but still do not meet the ultimate objective.

A fourth report (Omang, Parrett, and Hull, 1986) gives techniques for estimating flood magnitudes having recurrence intervals of as much as 100 years for ungaged sites based on data through 1983. Equations were developed that relate flood magnitudes to basin characteristics and channel geometry. The estimating equations developed were an improvement over equations of previous reports. However, with additional record available from the newer network of stations, even better areal boundary definition and reliability are anticipated.

PROGRAM OPERATION

At each crest-stage gaging station, one or more standard Geological Survey crest-stage gages record the maximum stage reached by the water surface. Many stations are located at highway culverts, which are used as control structures for rating the peak discharge. If the peak discharge is not measured, it can be computed from the shape of the channel near the culvert, the culvert geometry, and the water-surface profile upstream and downstream from the culvert at the time of the peak flow. The water-surface profile, obtained from marks recorded on the crest-stage gages, commonly is supplemented by nearby high-water marks along the stream channel. Because of varying conditions from year to year, the discharge determined from similar gage heights may vary.

Flow records for continuous-record gaging stations, which are a part of other cooperative programs, supplement the crest-stage network. The continuous-record gaging stations help to establish the date of recorded peak stages and help to detect peak discharges when the crest-stage gages may not be functioning properly. Climatological data published by the National Weather Service are also used to help determine the dates of peak discharge.

The crest-stage gaging stations provide information from drainage areas that range in size from less than 1 mi² to several hundred square miles. The areas represent various hydrologic conditions. During water year 1989, the active-station network included 26 stations having drainage areas less than 1 mi², 85 stations having areas from 1 to 10 mi², 38 stations having areas from 10 to 50 mi², and 9 stations having areas of more than 50 mi².

Operation of the crest-stage gages to record peak stages continues to be the primary phase of work. Periodic visits are made to service the gages and to record the peak stages that have occurred since the last visit. Changes in channel, culvert, and control conditions are also noted. Another operation includes closed traverse surveys to determine any changes in the altitude of the gages.

STATION DATA

All stations are listed in downstream order, first for the Missouri River basin and then for the Columbia River basin. For each station, the first entry is the permanent station number, which consists of a two-digit Part number and a six-digit downstream order number. The Part number designates the major river basin--Part 06 is for the Missouri River basin and Part 12 is for the Columbia River basin. The station number is followed by the station name.

Records for each station consist of two parts--the station description and the tabular data. The station description includes the station location, drainage area, period of record available, and type of gage including altitude of gage above sea level. The tabular data consist of annual maximum gage height and discharge listed by water year and date. The date for each annual maximum discharge is as near the actual day of peak flow as can be determined from available data.

Data for annual peak discharge in the tables are subject to revision. A gage-height or peak-discharge listing of "unknown" means a reliable figure is not available.

Explanation of the footnotes used in the station data tabulations are listed below.

- a Prior to installation of gage.
- b Estimate.
- c Backwater.
- d No evidence of flow during year.
- e Includes an estimated 15 ft³/s bypass flow.
- f Peak discharge did not reach bottom of gage.
- g Maximum observed for the year.
- h Combination of flow in Monture and Dunham Creeks.
- < Less than.

MISSOURI RIVER BASIN

06013500 Big Sheep Creek below Muddy Creek, near Dell, MT

Location.--Lat 44°39'19", long 112°46'41", in SE1/4 sec.35, T.13 S., R.10 W., Beaverhead County, Hydrologic Unit 10020001, 6.5 mi southwest of Dell.

Drainage area.--278 mi².

Records available.--May 1946 to September 1953 (continuous record), June 1959 to September 1976 (peak record), October 1976 to September 1979 (continuous record), 1980 to current year.

Gage.--Water-stage recorder reinstalled June 24, 1959. Altitude of gage is 6,390 ft, from topographic map.

Annual maximum data.--
