HYDROLOGIC AND HYDRAULIC ANALYSES AT AKIN BRANCH AND CAYCE VALLEY BRANCH, COLUMBIA, TENNESSEE

By George S. Outlaw

Abstract

The U.S. Geological Survey, in cooperation with the City of Columbia, Tennessee, conducted hydrologic and hydraulic analyses at Akin Branch and Cayce Valley Branch in the Little Bigby Creek watershed, Columbia, Tennessee, from 1990 through 1991. Results of the analyses can be used by city planners in the development of plans to replace several deteriorating and inadequate drainage structures.

Akin Branch and Cayce Valley Branch drain small watersheds of 1.69 and 1.04 square miles, respectively. Flood discharges for 5-, 10-, and 25-year recurrence-interval storm events were calculated at the stream mouths using flood-frequency relations developed for use at small urban streams in Tennessee. For each stream, flood discharges at locations upstream from the mouth were calculated by subdividing the watershed and assigning a percentage of the discharge at the mouth, based on drainage area, to each subarea.

Flood profiles for the selected recurrence-interval flood discharges were simulated for Akin Branch and Cayce Valley Branch for existing conditions and conditions that might exist if drainage improvements such as larger culverts and bridges and channel improvements are constructed. The results of the simulations were used to predict changes in flood elevations that might result from such drainage improvements. Analyses indicate that reductions in existing flood elevations of as much as 2.1 feet for the 5-year flood at some sites on Akin Branch and as much as 3.8 feet for the 5-year flood at some sites on Cayce Valley Branch might be expected with the drainage improvements.

INTRODUCTION

Local flooding due to poor drainage conditions affects many communities in Tennessee. Frequently, local flooding is caused and enhanced by the encroachment of buildings and other structures into natural flood channels, and the constriction of channels at culverts and bridges. Such conditions are present within the Little Bigby Creek watershed of Maury County, Tennessee (fig. 1), and particularly in the urban reaches of two tributaries, Akin Branch and Cayce Valley Branch, in the City of Columbia.

The U.S. Geological Survey (USGS), in cooperation with the City of Columbia, conducted a hydrologic and hydraulic study of Akin Branch and Cayce Valley Branch to determine existing conditions which lead to local flooding, and to evaluate hydrologic and hydraulic conditions that might exist with possible drainage improvements. Objectives of the study were to estimate flood discharges and flood profiles along these two streams for storms with recurrence intervals of 5, 10, and 25 years under present

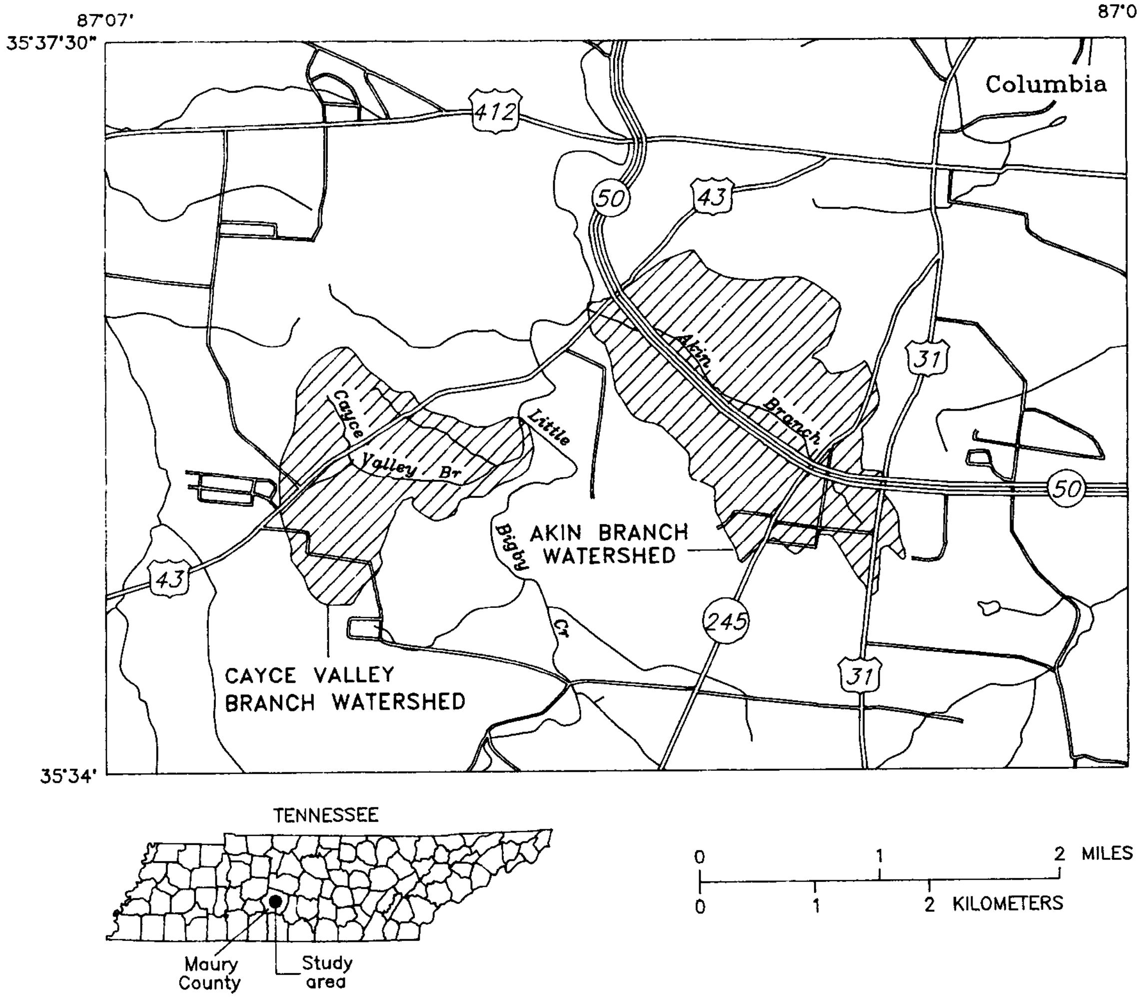

Figure 1. Location of the Akin Branch and the Cayce Valley Branch watersheds, Columbia, Tennessee.

and possible future conditions that include larger culverts and bridges and other channel improvements. The study is one of several urban hydrology investigations being conducted by the USGS in Tennessee and in other states.

Purpose and Scope

This report presents data on the hydraulic characteristics of Akin Branch and Cayce Valley Branch and estimates of flood discharge at numerous points along the streams. The report describes model-simulated flood profiles for 5-, 10-, and 25-year storms, and includes an analysis of changes in flood profiles resulting from possible drainage improvements.

Approach

The following approach was used to meet the objectives of the investigation:

1. The watershed boundary and amount of impervious area within Akin Branch and Cayce Valley Branch watersheds were determined from USGS topographic maps and validated with field data.

2. Hydraulic characteristics of segments of the channels of Akin Branch and Cayce Valley Branch were determined from field surveys. These characteristics included cross-sectional areas, bed profiles, roughness coefficients, and location and dimensions of bridges and culverts.

3. Flood discharges for 5-, 10-, and 25-year recurrence interval storm events were computed for Akin Branch and Cayce Valley Branch using equations developed by Robbins (1984).

4. The USGS Water-Surface Profile (WSPRO) computation model (Shearman and others, 1986; Shearman, 1990) was used to compute flood profiles for 5-, 10-, and 25-year recurrence interval storm events for existing conditions at Akin Branch and Cayce Valley Branch.

5. WSPRO was used to study the effects of drainage improvements at Akin Branch and Cayce Valley Branch.

HYDROLOGIC AND HYDRAULIC ANALYSIS

Flood discharges with 5-, 10-, and 25-year recurrence intervals were estimated at the mouths of Akin Branch and Cayce Valley Branch using regional equations and techniques described by Robbins (1984). For each stream, flood discharges at locations upstream from the mouth were calculated by subdividing the watershed and assigning a percentage of the discharge at the mouth, based on drainage area, to each subarea. Robbins' equations were developed to estimate flood discharges along urban streams in Tennessee with drainage areas from 0.21 to 24.3 mi^2. Using the flood discharges, flood profiles were computed with the WSPRO model. Critical depth was used as the starting elevation for the profile computations. The effects of culverts, bridges, and other obstructions in the channel were included in the computation of the profiles for each flood discharge.

The following equations developed by Robbins (1984) were used to estimate flood discharges.

$$Q_5 = 5.55(A)^{0.75}(IA)^{0.44}(P_{2\_24})^{2.53}$$

$$Q_{10} = 11.8(A)^{0.75}(IA)^{0.43}(P_{2\_24})^{2.12}$$

$$Q_{25} = 21.9(A)^{0.75}(IA)^{0.39}(P_{2\_24})^{1.89}$$

where

Q_n is the estimated flood discharge, in cubic feet per second, for the indicated recurrence interval; n, in years;

A is the area of the watershed, in square miles;

IA is the percentage of the drainage area that is impervious to infiltration of rainfall; and

P_{2_24} is the 2-year 24-hour rainfall, in inches.

Values for watershed area and percentage of impervious area of the watershed were determined using topographic maps, aerial photographs, and field data. The rainfall for the 2-year 24-hour recurrence interval was estimated as 3.6 inches using maps developed for Tennessee by the U.S. Department of Commerce and published by Robbins (1984).

Flood profiles were calculated using the WSPRO model. The model can be used to analyze one-dimensional, gradually varied, steady flow in open channels. WSPRO also can be used to analyze flow through bridges and culverts, and to simulate road overflow.

WSPRO data requirements include: discharge, channel cross sections and distances, bridge and culvert geometry, road surface elevations, and channel-roughness coefficients. Discharges were estimated using equations developed by Robbins (1984). Channel cross sections and distances, bridge and culvert geometry, road surface elevations, and channel-roughness coefficients were obtained from field surveys.

Once the model is calibrated using observed storm data, the hydraulic model can be used to study the effects caused by changes in channel characteristics on the flood profile for a particular flood discharge. For example, changes in the size and aperture of bridges and culverts can be simulated to determine the effects on the flood profiles.

Akin Branch

Akin Branch drains a small urban watershed with a contributing drainage area of 1.7 mi^2. At present, residential and commercial development account for about 10 percent of the basin. However, the potential for continued development could result in 20 percent of the contributing drainage area becoming impervious to infiltration of rainfall in the future. This value of imperviousness was used to estimate flood discharges for future developed conditions.

The study reach (fig. 2) begins at a point approximately 59 feet downstream from the culvert at James Campbell Boulevard (structure 1), and extends upstream approximately 7,300 feet (measured along the centerline of the stream) to a point just upstream from the culvert under the lumberyard at the corner of Highland Avenue and Nicholas Long Drive (structure 13) (table 1). The study reach contains a total of 13 culverts and bridges.

Flood Discharges

Flood discharges for Akin Branch were computed by assigning a percentage of the total basin flood discharge to each basin subarea based on the percentage of the watershed occupied by the subarea (fig. 3). The watershed was subdivided on the basis of topography and the location of tributaries and culverts draining into the creek. Flood discharges for the 5-, 10-, and 25-year recurrence intervals for each basin

Table 1. Akin Branch culvert and bridge inventory

[Stream stationing is given in hundreds of feet plus feet from a point 59 feet downstream from James Campbell Boulevard]

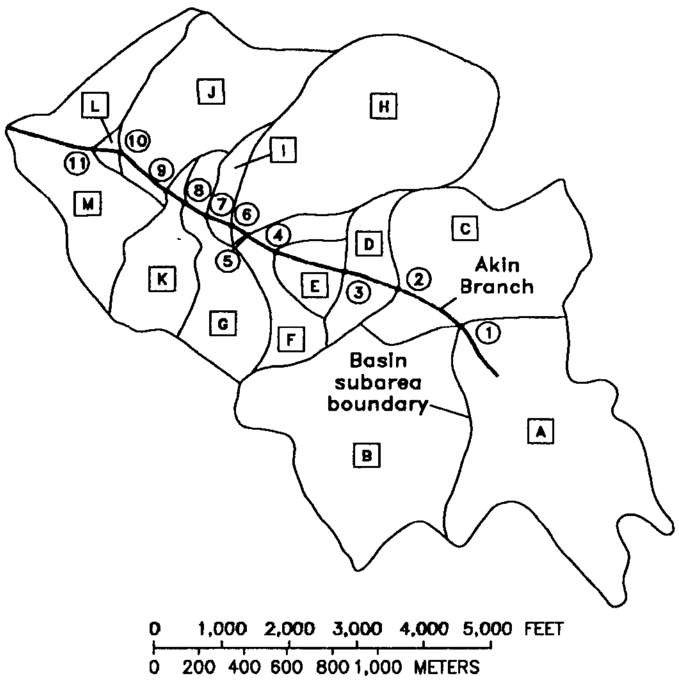
Structure number	Structure name	Stream stationing	Structure description
1	James Campbell Boulevard culvert.	0+59 - 2+00	Two-barrel concrete box culvert. Average barrel inlet, 8 feet x 6 feet. Length, 141 feet.
2	Store entrance culvert	9+10 - 9+50	Two-barrel concrete box culvert. Average barrel inlet, 8 feet x 6.6 feet. Length, 40 feet.
3	Bank entrance culvert	13+37 - 13+63	Three-barrel concrete box culvert. Average barrel inlet, 8.5 feet x 5.5 feet. Length, 26 feet.
4	Wedgewood Drive bridge	15+85 - 16+07	Single span concrete bridge. Inlet, 15.5 feet x 4 feet. Length, 22 feet.
5	Alpine Drive bridge	20+00 - 20+22	Single span concrete bridge. Inlet, 15 feet x 5 feet. Length, 22 feet.
6	Store entrance culvert	22+50 - 22+84	Two-barrel concrete box culvert. Barrel inlet, 8 feet x 8.2 feet. Length, 34 feet.
7	Shady Brook Lane culvert	25+50 - 26+21	One-barrel concrete box culvert. Barrel inlet, 14 feet x 5 feet. Length, 71 feet.
8	Mall entrance culvert	30+23 - 32+18	One-barrel concrete box culvert. Barrel inlet, 14 feet x 4.4 feet. Length, 195 feet.
9	Mall parking lot culvert	35+80 - 42+20	One-barrel concrete box culvert. Barrel inlet, 14 feet x 5.1 feet. Length, 640 feet.
10	Brookmeade Road culvert	43+37 - 44+22	One-barrel concrete box culvert. Barrel inlet, 10 feet x 5.9 feet. Length, 85 feet.
11	Denise Drive culvert	55+10 - 55+44	One-barrel concrete box culvert. Barrel inlet, 12 feet x 6.8 feet. Length, 34 feet.
12	Highland Avenue culvert	69+44 - 69+84	One-barrel corrugated metal pipe. Average pipe diameter, 3.5 feet. Length, 40 feet.
13	Lumberyard culvert	69+90 - 71+70	One-barrel corrugated metal pipe. Average pipe diameter, 4.5 feet. Length, 180 feet.

subarea were calculated using the equations developed by Robbins (1984). These values were input to the WSPRO model for the calculation of the water-surface profiles.

Flood Profiles

The hydraulic model was calibrated for existing conditions based on high-water marks that were obtained shortly after the flood of February 3, 1990 (table 2). The recurrence interval of this flood was approximately 5 years (fig. 4). Highwater marks shown for the February 3, 1990 flood in the vicinity of Denise Drive (stream station 55+00) are higher than the completed profiles because a new culvert was constructed at that location between February 3, 1990, and the time the profiles were computed.

AKIN BRANCH WATERSHED



EXPLANATION

① NODE AND NUMBER

[B] BASIN SUBAREA DESIGNATION

URBAN RUNOFF EQUATIONS (Robbins, 1984)

$Q_5 = 5.55\,(A)^{0.75}\,(IA)^{0.44}\,(P2\_24)^{2.53}$

$Q_{10} = 11.8\,(A)^{0.75}\,(IA)^{0.43}\,(P2\_24)^{2.12}$

$Q_{25} = 21.9\,(A)^{0.75}\,(IA)^{0.39}\,(P2\_24)^{1.89}$

P2_24 = 3.6 inches

Where

Q_n is the estimated flood discharge, in cubic feet per second, for the indicated recurrence interval, in years;
A is the area of the watershed, in square miles;
IA is the percentage of the drainage area that is impervious to infiltration of rainfall; and
P2_24 is the 2-year 24-hour rainfall amount, in inches.

Average basin impervious area is 20 percent
Total basin area is 1.69 square miles

Total basin flows

Q_5 = 5.55 x 1.483 x 3.74 x 25.6 =790 cubic feet per second
Q_{10} = 11.8 x 1.483 x 3.63 x 15.1 =960 cubic feet per second
Q_{25} = 21.9 x 1.483 x 3.22 x 11.3 =1,180 cubic feet per second

Figure 3. Akin Branch flood discharges for selected recurrence intervals.

Using the calibrated model for the February 3 flood discharge, flood profiles were computed for existing channel conditions for 5-, 10-, and 25-year recurrence intervals (fig. 4a-4g). Selected output from the hydraulic model has been tabulated to aid in interpretation of results (table 3). The computed flood profiles indicate road overtopping of as much as 2.5 feet at Wedgewood Drive and as much as 1.5 feet at Alpine Drive for the 25-year flood. The profiles also indicate that backwater (hydraulic head buildup) of about 1.4 feet occurs at the upstream side of Alpine Drive. These adverse hydraulic conditions are attributed to undersized structures and flood-plain development.

Simulation of Effects of Alternative Drainage Structures

The calibrated hydraulic model was used to simulate the flood profiles at Akin Branch that would result from possible alternative designs for selected drainage structures. Data on existing structure sizes are listed in table 1, and the alternative drainage improvement designs evaluated using the model are described below for model simulations 1 through 3.

Simulation 1: A three-barrel concrete box culvert with a total barrel width of 24 feet, barrel height of 7 feet, and culvert length of 30 feet was simulated at Wedgewood and Alpine Drives.

Table 2. Akin Branch high-water mark elevations for the February 3, 1990 flood

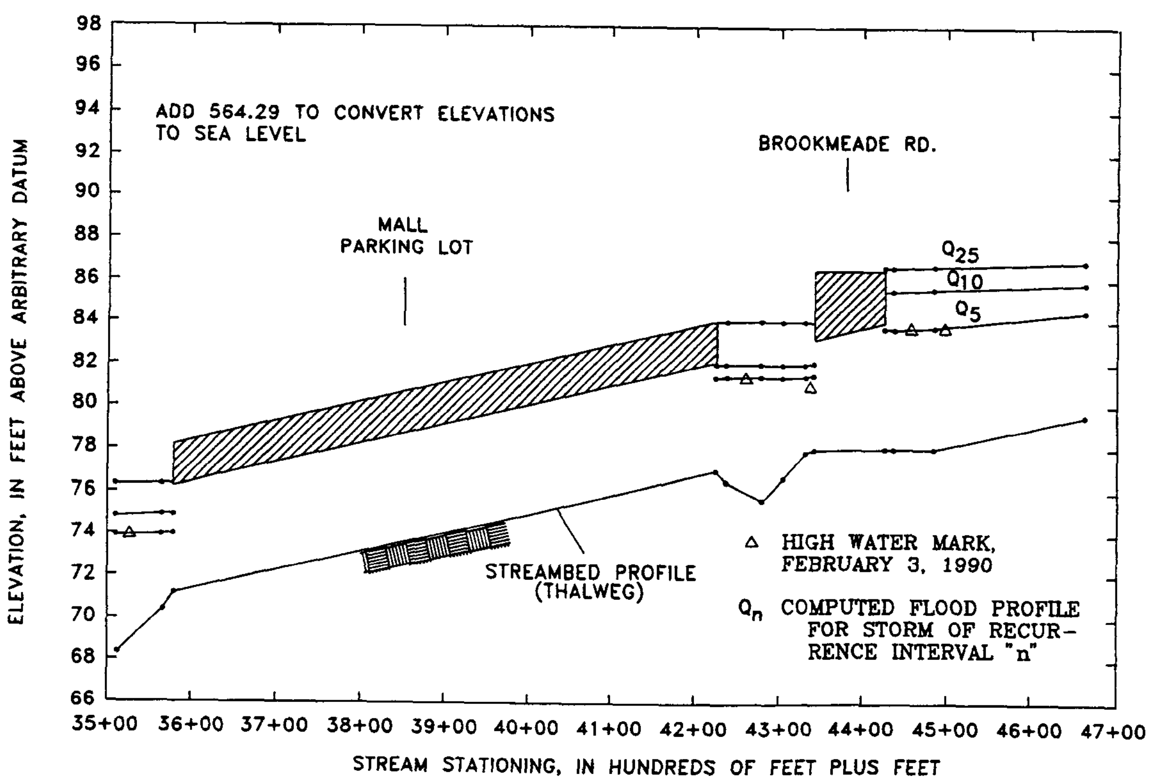

Figure 4d. Computed flood profiles, existing conditions, with February 3, 1990, high-water marks for Akin Branch--Continued.

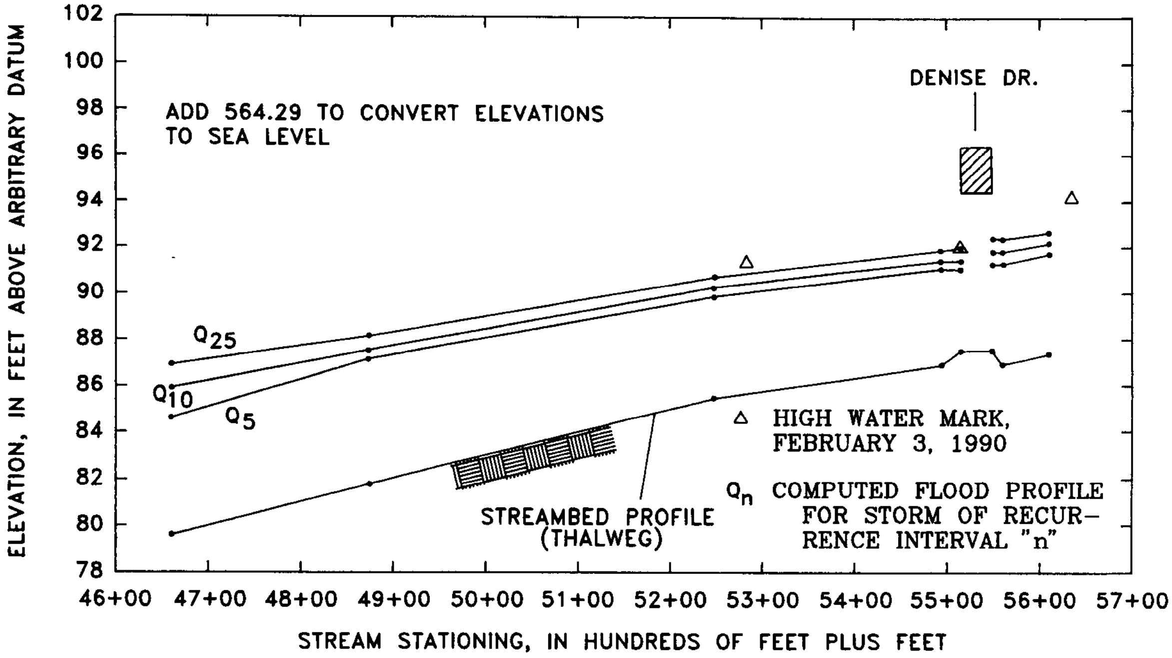

Figure 4e. Computed flood profiles, existing conditions, with February 3, 1990, high-water marks for Akin Branch--Continued.

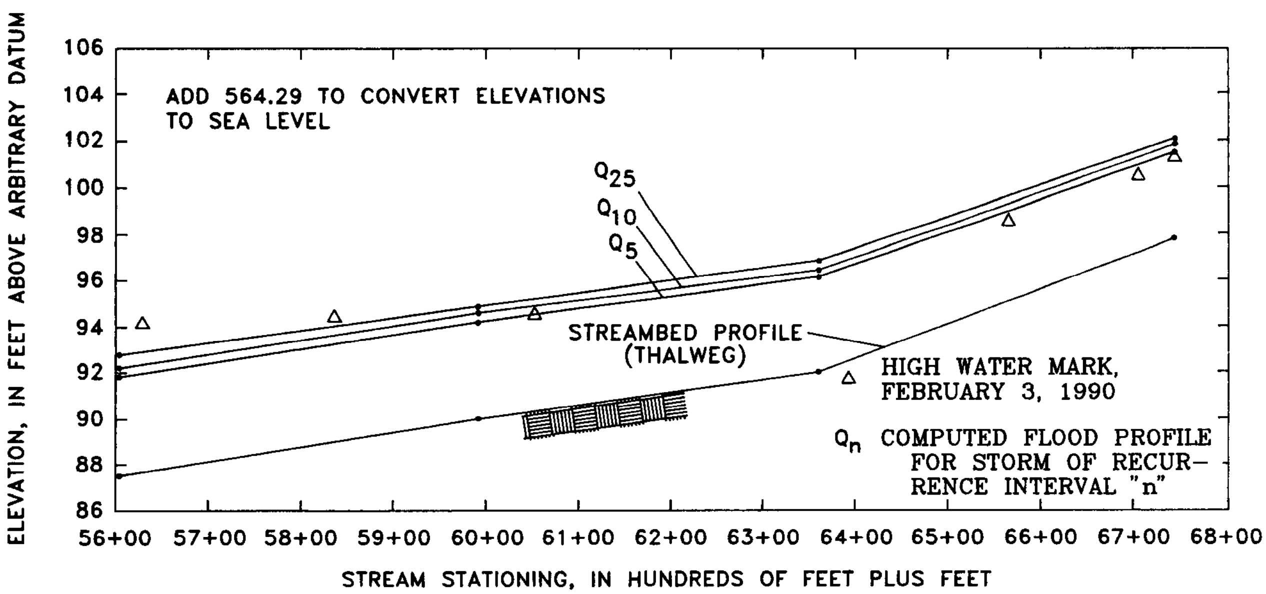

Figure 4f. Computed flood profiles, existing conditions, with February 3, 1990, high-water marks for Akin Branch--Continued.

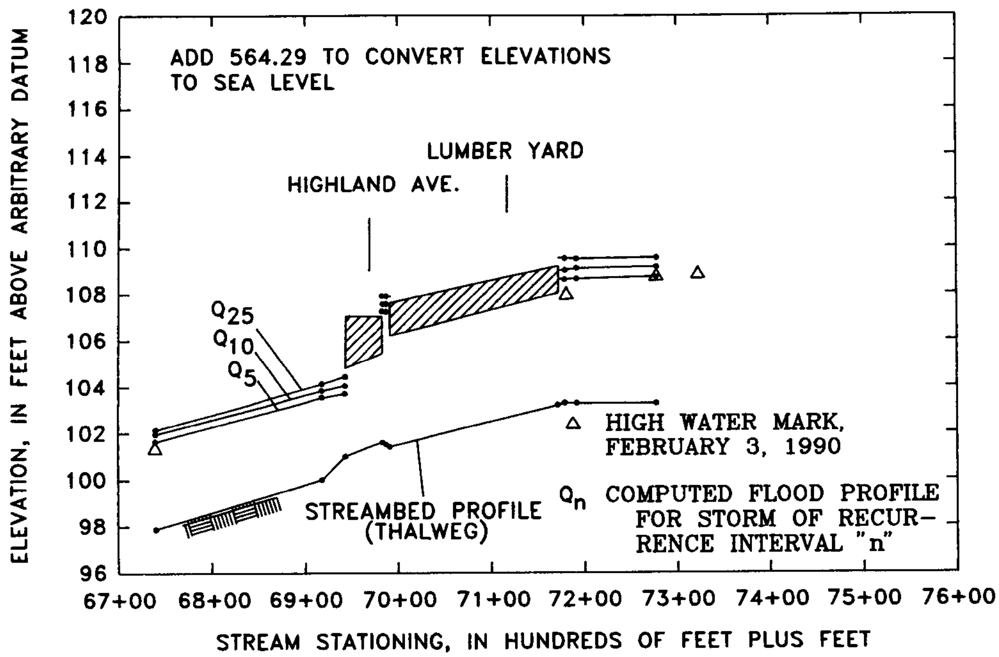

Figure 4g. Computed flood profiles, existing conditions, with February 3, 1990, high-water marks for Akin Branch--Continued.

Simulation 2: A three-barrel concrete box culvert with a total barrel width of 21 feet, barrel height of 6.5 feet, and length of 30 feet was simulated at Wedgewood Drive. A three-barrel concrete box culvert with a total barrel width of 22.5 feet, barrel height of 6.5 feet, and length of 30 feet was simulated at Alpine Drive.

Simulation 3: A three-barrel concrete box culvert with a total barrel width of 24 feet, barrel height of 6 feet, and culvert length of 30 feet was simulated at Wedgewood Drive with maximum channel excavation of 0.8 foot between stations 14+25 and 16+48. A three-barrel concrete box culvert with a total barrel width 24 feet, barrel height of 6 feet, and culvert length of 30 feet was simulated at Alpine Drive.

The simulated flood profiles for the three conditions (fig. 5, 6, and 7) indicate that during the 25-year flood: Drainage improvements modeled in simulation 1 would result in an increase of 0.3 foot in the water-surface elevation upstream from Wedgewood Drive and a decrease of 0.7 foot in the water-surface elevation upstream from Alpine Drive (table 4, fig. 5). No culvert overtopping would occur. Drainage improvements modeled in simulation 2 would result in an increase of 0.6 foot in the water-surface elevation upstream from Wedgewood Drive and a decrease of 0.2 foot in the water-surface elevation upstream from Alpine Drive (table 5, fig. 6). About one-half foot of culvert overtopping would occur at Wedgewood Drive. Drainage improvements modeled in simulation 3 would result in a decrease of 0.2 foot in the water-surface elevation upstream from Wedgewood Drive and a decrease of 0.9 foot in the water-surface elevation upstream from Alpine Drive (table 6, fig. 7). Two feet of culvert overtopping would occur at Wedgewood Drive.

For existing conditions, culvert overtopping of approximately 2.5 feet at Wedgewood Drive and 1.5 feet at Alpine Drive can be expected during the 25-year flood. These analyses indicate that culvert overtopping at Wedgewood Drive is necessary to reduce upstream water-surface elevations for existing downstream conditions.

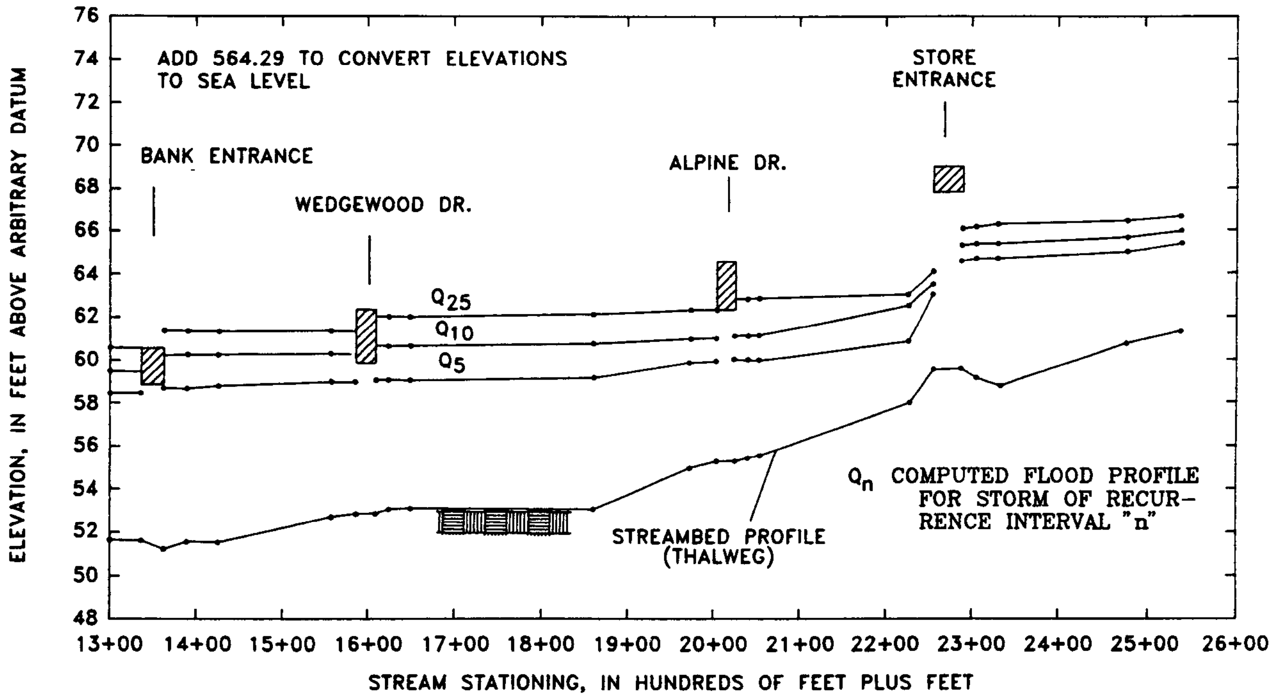

Figure 5. Computed flood profiles for Akin Branch, simulation 1.

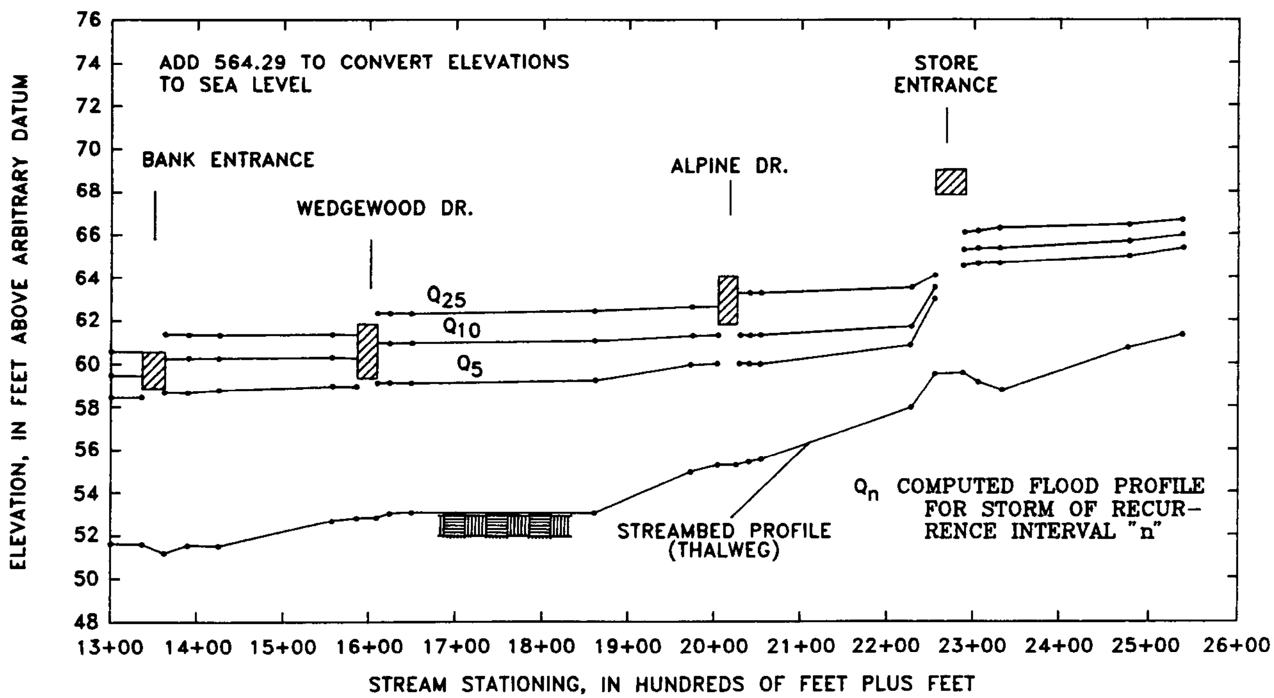

Figure 6. Computed flood profiles for Akin Branch, simulation 2.

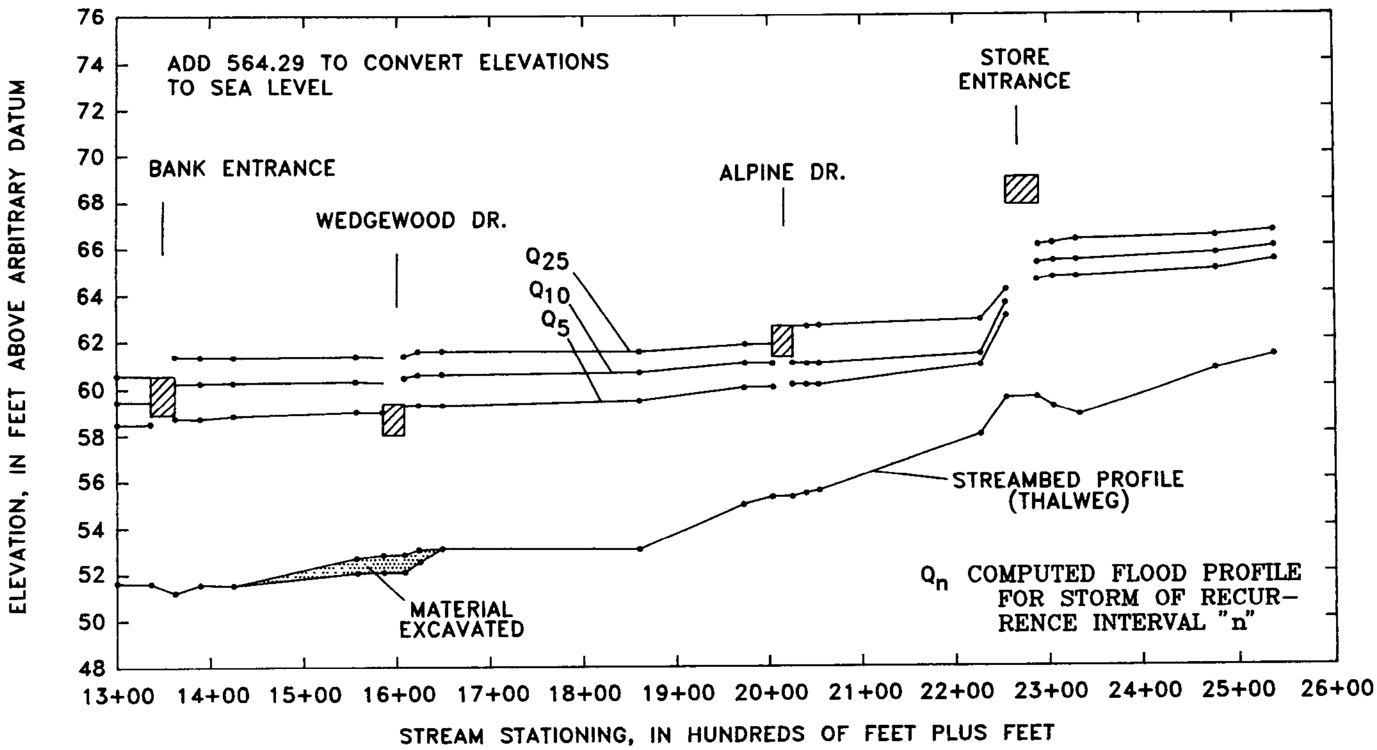

Figure 7. Computed flood profiles for Akin Branch, simulation 3.

Cayce Valley Branch

Cayce Valley Branch drains a small urban watershed with a contributing drainage area of 1.04 mi^2. At present, residential and commercial development account for about 5 percent of the basin. However, the potential for continued development could result in 10 percent of the contributing drainage area becoming impervious to infiltration of rainfall in the future. This value of imperviousness was used to estimate flood discharges for future developed conditions.

The study reach (fig. 8) begins at a point approximately 100 feet downstream from Whitney Drive (structure 1), and extends upstream approximately 5,000 feet (measured along the centerline of the stream) to a point just upstream of the culvert under Jewell Drive (structure 11) (table 7). The study reach contains a total of 11 culverts and bridges.

Flood Discharges

Flood discharges for Cayce Valley Branch were computed by assigning a percentage of the total basin flood discharge to each basin subarea based on the percentage of the watershed occupied by the subarea (fig. 9). The watershed was subdivided on the basis of topography and the location of tributaries draining into the creek. Flood discharges for the 5-, 10-, and 25-year recurrence intervals for each basin subarea were calculated using the equations developed by Robbins (1984). These values were input to the WSPRO model for the calculation of water-surface profiles.

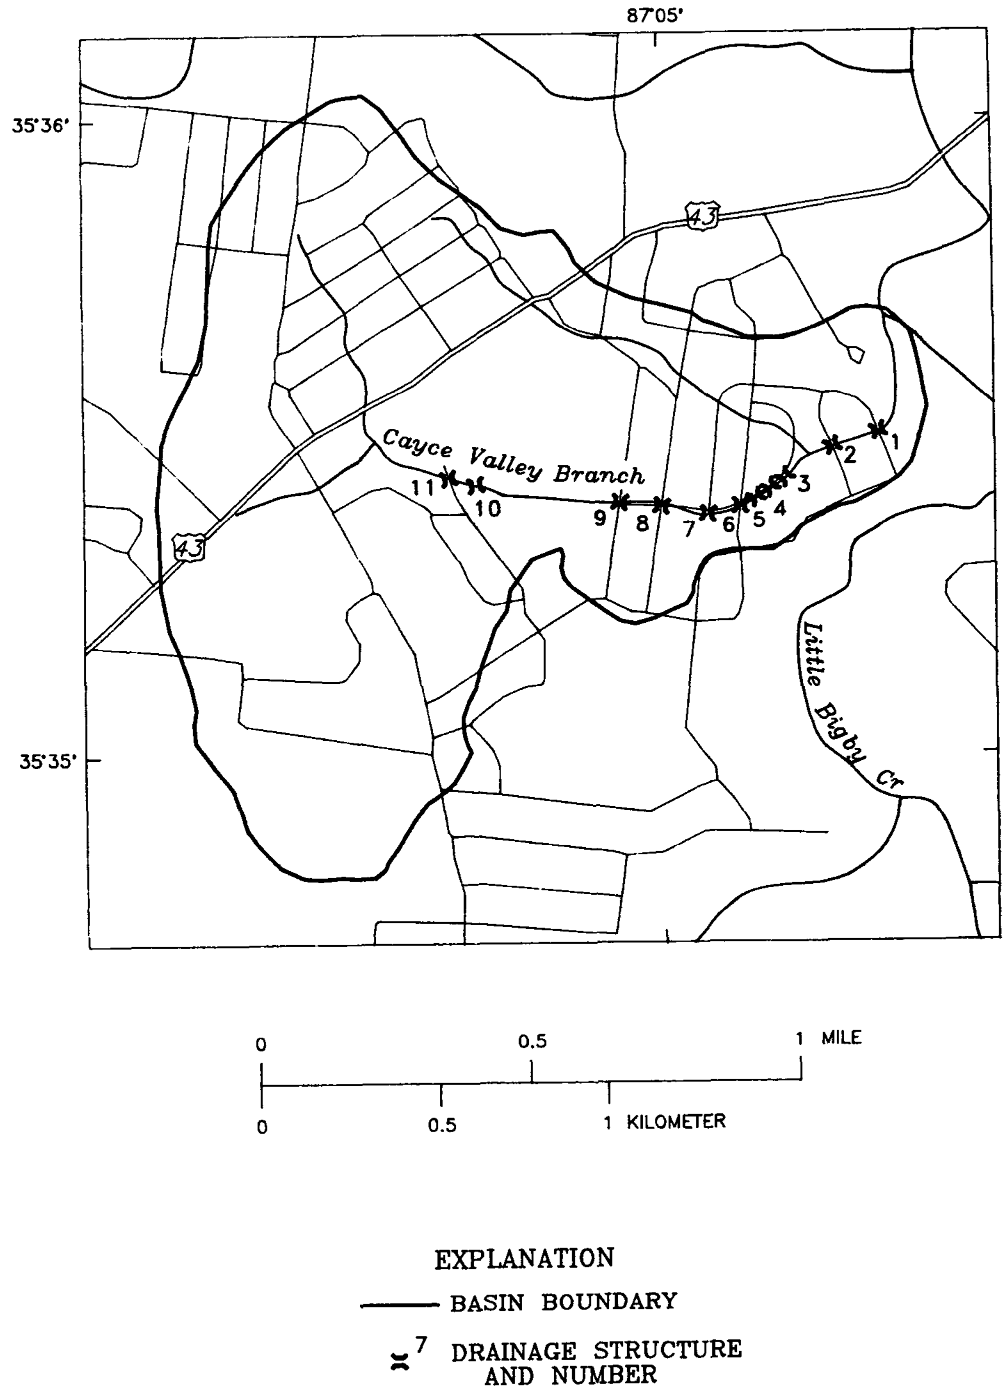

Figure 8. Location of drainage structures in the Cayce Valley Branch study reach.

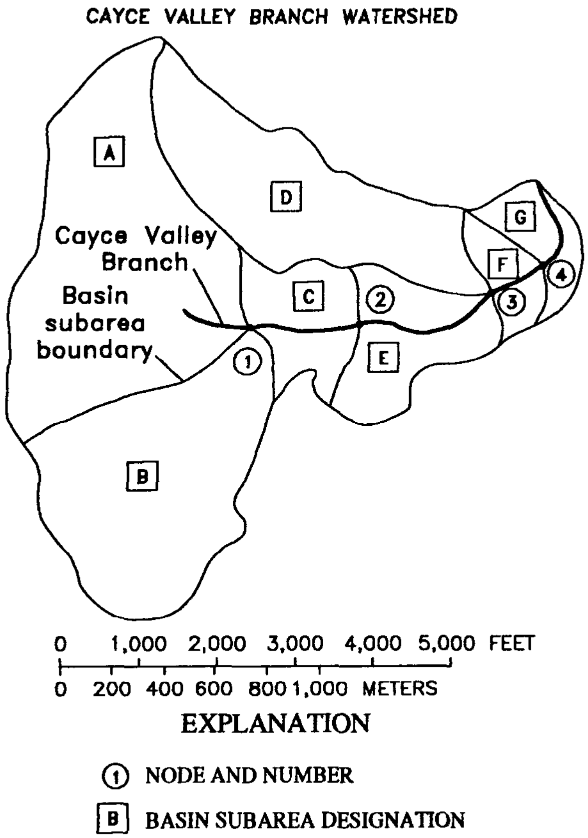
Table 7. Cayce Valley Branch culvert and bridge inventory

[Stream stationing is given in hundreds of feet plus feet from a point 412 feet downstream from Whitney Drive]

Structure number	Structure name	Stream stationing	Structure description
1	Whitney Drive culvert.	4+12 - 4+46	Two-barrel concrete pipe culvert. Barrel diameter, 4 feet. Length, 34 feet.
2	Mariner Drive culvert.	8+47 - 8+86	Three-barrel corrugated metal pipe culvert. Average barrel diameter, 4 feet. Length, 39 feet.
3	Foot bridge	12+06 - 12+22	Two-barrel smooth metal pipe culvert. Barrel diameter, 2 feet. Length, 16 feet.
4	Private driveway culvert.	13+06 - 13+22	Two-barrel concrete box culvert. Average barrel inlet, 5.4 feet x 4.1 feet. Length, 16 feet.
5	Private driveway culvert.	18+58 - 18+75	Two-barrel concrete box culvert. Average barrel inlet, 5.8 feet x 4.2 feet. Length, 17 feet.
6	Manor Road culvert.	21+16 - 21+36	One-barrel concrete box culvert. Barrel inlet, 13.6 feet x 4.1 feet. Length, 20 feet.
7	Cayce Valley Drive culvert.	24+36 - 24+68	One-barrel concrete box culvert. Barrel inlet, 12 feet x 3.2 feet. Length, 32 feet.
8	Windemere Drive culvert.	28+40 - 28+66	One-barrel concrete box culvert. Barrel inlet, 12 feet x 3.7 feet. Length, 26 feet.
9	Timberwood Drive culvert.	33+40 - 33+64	One-barrel concrete box culvert. Barrel inlet, 12 feet x 4.2 feet. Length, 24 feet.
10	Farm driveway culvert.	47+09 - 47+22	One-barrel timber deck culvert. Inlet, 9.2 feet x 4.7 feet. Length, 13 feet.
11	Jewell Drive culvert.	49+64 - 49+77	Two-barrel, corrugated metal pipe culvert. Barrel cross-sectional area, 11.5 ft^2. Length, 13 feet.

Flood Profiles

Flood profiles were computed for existing channel conditions for 5-, 10-, and 25-year recurrence interval floods at Cayce Valley Branch (fig. 10a-10d). No observed flood data are available for Cayce Valley Branch to use in calibrating the WSPRO model. The computed profiles indicate road overtopping of as much as 0.9 foot at Whitney Drive and 0.9 foot at Mariner Drive for the 25-year flood. The flood profiles also indicate the occurrence of backwater of as much as 5.3 feet at the upstream side of Whitney Drive and as much as 2.5 feet at Mariner Drive for the 25-year flood discharge. Hydraulic problems at these locations are attributed to undersized structures at both streets and a clogged channel downstream from Whitney Drive. Selected output from the hydraulic model has been tabulated to aid in interpretation of results (table 8).



BASIN SUBAREA FLOOD DISCHARGES

Basin subarea	Area, in square miles	Percent of total flow	Discharge, in cubic feet per second, for indicated recurrence interval, in years		
			Q_5	Q_{10}	Q_{25}
A	0.345	33.2	135	165	210
B	.256	24.7	100	120	155
C	.072	6.9	25	35	40
D	.206	19.8	80	100	125
E	.090	8.7	35	45	55
F	.032	3.0	10	15	20
G	.039	3.7	15	20	25

BASIN FLOOD DISCHARGES

Node number	Stream stationing	Discharge, in cubic feet per second, for indicated recurrence interval, in years		
		Q_5	Q_{10}	Q_{25}
0 - 1	49+93 - 48+36	135	165	210
1 - 2	48+36 - 33+22	260	320	405
2 - 3	33+22 - 11+96	295	365	460
3 - 4	11+96 - 4+00	385	480	605

URBAN RUNOFF EQUATIONS (Robbins, 1984)

$Q_5 = 5.55\,(A)^{0.75}\,(IA)^{0.44}\,(P2\_24)^{2.53}$

$Q_{10} = 11.8\,(A)^{0.75}\,(IA)^{0.43}\,(P2\_24)^{2.12}$

$Q_{25} = 21.9\,(A)^{0.75}\,(IA)^{0.39}\,(P2\_24)^{1.89}$

P2_24 = 3.6 inches

Where

Qn is the estimated flood discharge, in cubic feet per second, for the indicated recurrence interval, in years;

A is the area of the watershed, in square miles;

IA is the percentage of the drainage area that is impervious to infiltration of rainfall; and

P2_24 is the 2-year 24-hour rainfall amount, in inches.

Average basin impervious area is 10 percent
Total basin area is 1.04 square miles

Total basin flows

$Q_5 = 5.55 \times 1.028 \times 2.75 \times 25.6 = 400$ cubic feet per second

$Q_{10} = 11.8 \times 1.028 \times 2.69 \times 15.1 = 495$ cubic feet per second

$Q_{25} = 21.9 \times 1.028 \times 2.45 \times 11.3 = 625$ cubic feet per second

Simulation of Effects of Alternative Drainage Structures

The hydraulic model was used to simulate the flood profiles at Cayce Valley Branch resulting from possible alternative designs for selected drainage structures. Data on existing structure sizes are listed in table 7, and the alternative drainage improvement designs evaluated using the model are described below for model simulations 1 and 2.

Simulation 1: A concrete box culvert with a barrel width of 10 feet, barrel height of 5 feet, and culvert length of 30 feet was simulated at Whitney Drive. A concrete box culvert with a barrel width of 10 feet, barrel height of 4.5 feet, and culvert length of 30 feet was simulated at Mariner Drive.

Simulation 2: A concrete box culvert with a barrel width of 10 feet, barrel height of 6 feet, and length of 30 feet was simulated at Whitney Drive. A concrete box culvert with a barrel width of 12 feet, barrel height of 4.5 feet, and length of 30 feet was simulated at Mariner Drive.

The simulated flood profiles for the two conditions (figs. 11 and 12) indicate that during a 25-year flood: Drainage improvements modeled in simulation 1 would result in a decrease of 0.6 foot in water-surface elevation upstream from Whitney Drive and a decrease of 0.3 foot in the water-surface elevation upstream from Mariner Drive (table 9, fig. 11). Drainage improvements modeled in simulation 2 would result in a decrease of 0.8 foot in water-surface elevation upstream from Whitney Drive and a decrease of 0.4 foot in water-surface elevation upstream from Mariner Drive (table 10, fig. 12).

SUMMARY

A flood study was conducted at Akin Branch and Cayce Valley Branch in the Little Bigby Creek watershed during 1990 and 1991. Major elements of the study included: estimation of flood discharges at points along Akin Branch and Cayce Valley Branch for selected recurrence intervals, simulation of flood profiles corresponding to estimated flood discharges for existing conditions at Akin Branch and Cayce Valley Branch, analysis of changes to flood profiles likely to result from possible drainage improvements such as enlarged box culverts at selected sites on Akin Branch and Cayce Valley Branch.

Flood discharges at the mouths of Akin Branch and Cayce Valley Branch were computed for 5-, 10-, and 25-year recurrence intervals using flood-frequency relations applicable to small urban streams in Tennessee. Flood discharges at points upstream from the mouth were estimated by subdividing the watershed and assigning a percentage of the discharge at the mouth, based on drainage area, to each subarea.

Flood profiles corresponding to the computed flood discharges were simulated for existing conditions at Akin Branch and Cayce Valley Branch using WSPRO, a computer model for water-surface profile computations. Computed flood profiles for existing conditions indicate excessive backwater problems at Wedgewood Drive and Alpine Drive on Akin Branch and at Whitney Drive and Mariner Drive on Cayce Valley Branch. On Akin Branch, these problems include road overtopping of as much as 2.5 feet at Wedgewood Drive and as much as 1.5 feet at Alpine Drive for the 25-year flood. The profiles also indicate backwater of about 1.4 feet at Alpine Drive. On Cayce Valley Branch, these problems include road overtopping of as much as 0.9 foot at Whitney Drive and Mariner Drive. Simulated backwater during a 25-year flood totaled as much as 5.3 feet at Whitney Drive and as much as 2.5 feet at Mariner Drive.

The USGS Water-Surface Profile (WSPRO) computation model was used to simulate the effects on existing flood profiles that might be expected if the culverts and bridges at these locations were enlarged. For the alternative designs studied, simulation 3 for Akin Branch indicated that the water-surface elevations during a 25-year flood would probably decrease by 0.2 foot upstream of Wedgewood Drive and would decrease by 0.9 foot upstream of Alpine Drive. For Cayce Valley Branch, simulation 2 indicated that the water-surface elevations during a 25-year flood would probably decrease by 0.8 foot upstream of Whitney Drive and decrease by 0.4 foot upstream of Mariner Drive. Reduced backwater was indicated at all locations.
