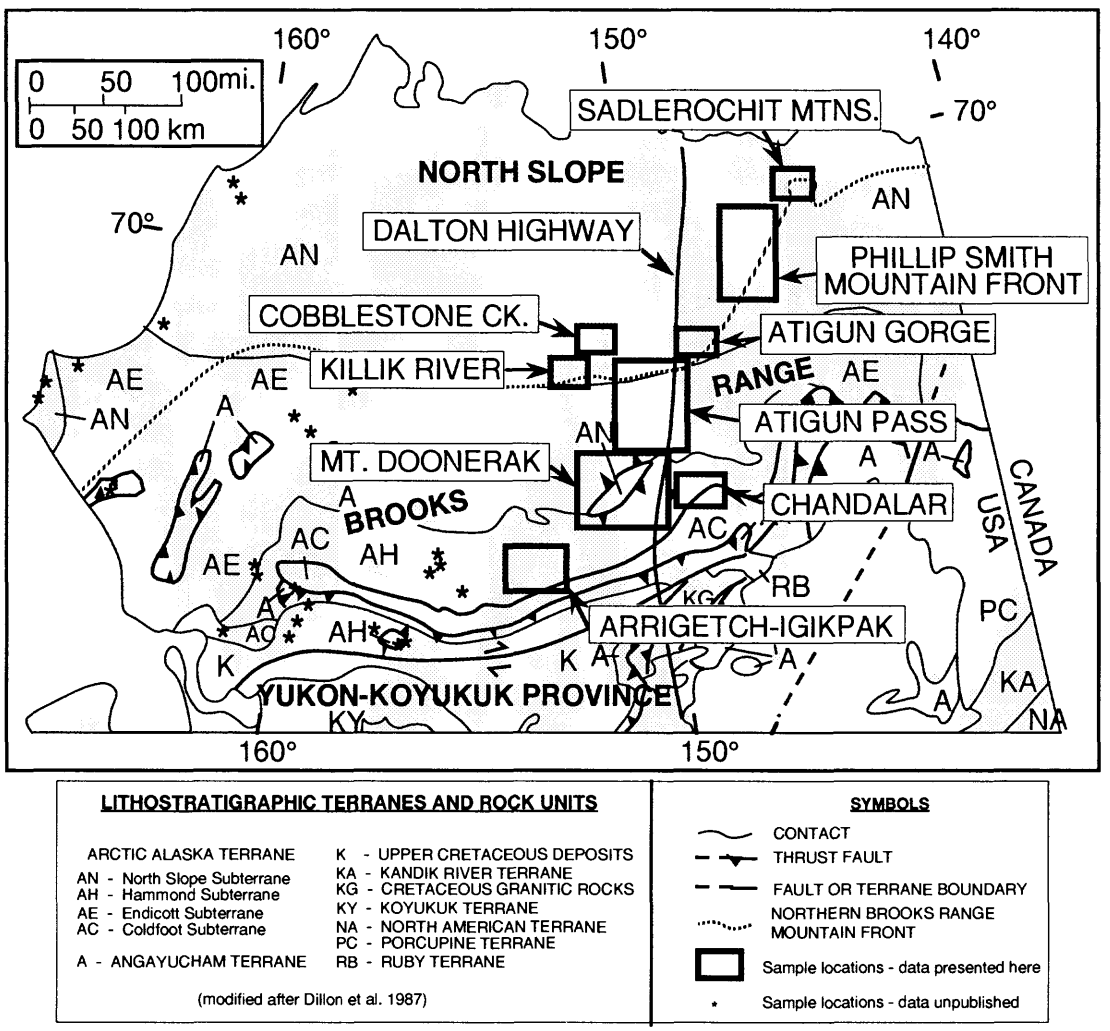
CONTENTS

INTRODUCTION

This is a preliminary report of apatite fission track analyses of 110 samples from the Brooks Range and North Slope foreland basin in northern Alaska. In order to help constrain the shallow-level thermal and techtonic history of the mountain belt and foreland basin, basement rocks (ie. granitic and gneissic rock units) and clastic sedimentary rocks were collected from several localities along the route followed by the Trans-Alaska Crustal Transect (TACT) (Fig. 1). Apatite fission track analysis (AFTA) was ideally suited for this project since the technique is applicable at temperatures less than ~110°C (or at depths less than ~3-4 km). All sampling was completed by the authors and other participants of the TACT project and all analyses were completed by John Murphy and Paul O'Sullivan in the research laboratories of the La Trobe University Fission Track Research Group, Melbourne, Australia.



LITHOSTRATIGRAPHIC TERRANES AND ROCK UNITS

ARCTIC ALASKA TERRANE
AN - North Slope Subterrane
AH - Hammond Subterrane
AE - Endicott Subterrane
AC - Coldfoot Subterrane
A - ANGAYUCHAM TERRANE

K - UPPER CRETACEOUS DEPOSITS
KA - KANDIK RIVER TERRANE
KG - CRETACEOUS GRANITIC ROCKS
KY - KOYUKUK TERRANE
NA - NORTH AMERICAN TERRANE
PC - PORCUPINE TERRANE
RB - RUBY TERRANE

(modified after Dillon et al. 1987)

Sample locations - data presented here
Sample locations - data unpublished

Figure 1. Location map showing sample locations. Data from samples collected for the TACT project (areas boxed) are presented here.

The data presented here is grouped geographically by the ten areas shown in Figure 1. Data from within each area is then shown by: 1) a table presenting sample details including location, elevation, stratigraphic unit, and rock type, 2) a table presenting the analytical results including the apatite fission track age and mean confined track length, 3) a table presenting the confined track length data, 4) data plots for each sample including radial plots, single-grain-age distributions, and confined track length distributions, and finally, 5) single-grain age reports for each sample.

The individual plots present the data graphically for each sample. When samples pass the Chi-squared test, the pooled age (groups all counts in a single calculation) is listed. When samples fail the Chi-squared test, the central age (weighted mean) is listed and marked by an *. Radial plots, explained in detail by Galbraith (1990) are used for the purpose of visually inspecting the value and precision of individual fission track ages of a sample and allow you to graphically inspect the presence of structure in the single grain age data presented in the single-grain-age distributions. The significance of confined track length distributions is explained in detail by Green et al. (1989).

The single-grain age reports for each sample show a listing of the individual grain ages, the resulting age and information used in determining the age. A guide to read the information is as follows:

89TM299A	-Sample number and information
IRRADIATION	-In-house number for grouping samples from the same irradiation package
SLIDE NUMBER	-Number of individual mount from irradiation package
No	-Number of each grain counted
Ns	-Number of spontaneous tracks counted
Ni	-Number of induced tracks counted
Na	-Number of area units counted in grain
Ratio	-Ratio of (NS/NI) for each grain
U(ppm)	-Uranium concentration of each grain (ppm)
RHOs	-Density of spontaneous tracks (per cm^2)
RHOi	-Density of induced tracks (per cm^2)
F.T.AGE (Ma)	-Individual fission track grain ages
P(chi squared)	-Statistical test for determining the presence of multiple grain populations, a probability of less than 5% indicates multiple grain populations
Correlation Coef.	-Statistical analysis suggesting how close all individual grain ages group together.
Variance of SQR	-Statistical comparison of values of NS or NI for all grains
Ns/Ni	-Pooled ratio of (Ns/Ni). Uses total number of spontaneous and induced tracks counted for whole sample. Value used in age calculation if sample is of a single population
Mean Ratio	-Average ratio of (Ns/Ni) for grains
POOLED AGE	-Age calculated using Ns/Ni (single population)
CENTAL AGE	-Age calculated Using weighted "Mean Ratio" (multiple populations; fail Chi-Squared test)

The stratigraphic nomenclature and stratigraphic ages used in this report are those recently summarized by Moore et al (1992) and Mull and Adams (1989). The geologic timescale of Harland et al. (1990) is utilized for radiometric ages. For an overview of the stratigraphy, structure, and tectonic history of northern Alaska, the reader is referred to the summary papers and maps of Mull (1982), Mull and Adams (1989), and Moore et al (1992) and the references therein.

TECHNIQUES

Apatites were separated from samples by conventional heavy liquid and magnetic techniques. The apatite separates were mounted in epoxy resin on glass slides, ground and polished to expose internal surfaces of the grains, then etched in 5M Nitric acid to reveal the fossil fission tracks. Neutron irradiations were carried out in a well thermalized neutron flux in the Australian Atomic Energy Commissions HIFAR reactor. All age determinations were completed using the external detector method (Hurford and Green, 1982). Thermal neutron fluences were monitored by counting tracks recorded in external muscovite detectors attached to NBS standard glass-SRM612. Standard and induced track densities were measured on mica external detectors and fossil track densities on internal mineral surfaces. Fission tracks in each mount were counted in transmitted light using a dry 80x objective at a total magnification of 1250x. Wherever possible 20-25 grains were counted on each mount. For further description of fission track counting methodology see Green (1986).

Fission track ages were calculated using the zeta calibration method and standard fission track age equation (Hurford and Green, 1982). Errors were calculated using the techniques of Green (1981). In samples with a significant spread in single grain ages, the "conventional analysis", (as defined by Green 1981), based purely on Poissonian variation, is not valid. In such cases, which can be detected by the Chi squared statistical test (Galbraith, 1981), the cental age (Galbraith, 1988) is reported. The Chi squared statistic indicates the probability that all grains counted belong to a single population of ages. A probability of less than 5% is evidence of a asymmetric spread of single grain ages. An asymmetric spread in individual grain ages can result either from inheritance of detrital grains from mixed detrital source areas, or from differential annealing in grains of different compositions (Green et al. 1989).

Lengths of confined tracks (Lal et al. 1969) were measured using the procedure outlined by Green (1986) and Green (1989). Only fully-etched and horizontal "confined tracks" were measured (Laslett et al. 1982) in grains with polished surfaces parallel to prismatic crystal faces. Measurements were made under similar conditions as those employed for age determination (e.g. 1250x, dry objective). The lengths of suitable tracks were measured using a projection tube and a Hipad™ digitizing tablet calibrated using a stage micrometer (with μm divisions). As many as ~100 tracks were measured from each sample.

ACKNOWLEDGEMENTS

We are grateful to the following colleagues for generously providing their experience, maps, samples, shipping, or laboratory facilities: E. Miller, T. Little, J. Lee, and P. Christiansen (Stanford University); S. Nelson, W. Nokleberg, J. Lull, S.Silva, W. Patton, A. Till, I. Tailleur, and S. Karl (US Geological Survey). We thank M. Robinson, R. Reifenstuhl and G. Mull (Alaska Division of Geological and Geophysical Surveys) for obtaining samples, and permission and funding for O'Sullivan to collect along the Dalton Highway. Major sources of funding, to whom we are grateful, were the donors of the Petroleum Research Fund, distributed by the American Chemical Society (#24101-AC2), ARCO Oil and Gas Co., Exxon Co., and Mobil Exploration and Producing Co. Mineral extractions were mainly conducted at La Trobe University by I. Asaac, M. Mitchell, W. Noble, R. Wahl, T. Bernecker, A. Rasa, and A. Verbeetin. Irradiation costs were subsidized by a grant to La Trobe University Fission Track Research Group from the Australian Institute of Nuclear Science and Engineering. We also thank A. Blythe and B. Patrick (University of California - Santa Barbara) for their participation in useful discussions and also for allowing access to unpublished manuscripts and data.

Sample Results - Sadlerochit Mountains

Typical yields for the samples were excellent. Due to relatively high uranium contents (>10 ppm), 3 of 5 mounts contained 100 or more confined tracks. All samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations so the pooled age is presented for each.

Table 2. Apatite fission track analytical results: Sadlerochit Mountains.

Sample Results - Philip Smith Mountain Front

Typical yields for the samples were quite good and in most cases 20-25 dateable grains were found on each mount. Due to relatively young ages and in some cases, low uranium content (<10 ppm), only 5 mounts contained 100 or more confined tracks and an additional 4 mounts had between 50 and 100 tracks. Five mounts had less than 20 confined tracks. For all samples it was determined that the dated grains represented a single population so the pooled age is presented for each.

Table 5. Apatite fission track analytical results: Philip Smith Mountain Front.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

Sample Results - Atigun Gorge

Typical yields for the samples were excellent. Due to relatively high uranium content (>10 ppm) 4 of 6 mounts contained 100 or more confined tracks. Most samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations.

Table 8. Apatite fission track analytical results: Atigun Gorge.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

Sample Results - Cobblestone Creek

Typical yields for the samples were excellent. Due to relatively high uranium contents (>10 ppm), 4 of 7 mounts contained 100 or more confined tracks. All samples from the Siksikpuk Formation and Nanushuk Group passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations. Samples from the Okpikruak Formation did not pass the Chi-squared test, indicating the dated grains represented a mixture of different age populations.

Sample Results - Killik River

Typical yields for the samples were excellent and in every case 20 grains were counted on each mount. Due to relatively high uranium concentrations (>20 ppm), at least 100 tracks were measured in every sample. Most samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations. For these samples the pooled fission track age is presented. The mean age is presented for those samples where it was determined that the dated grains did not represent a single age population.

Table 14. Track length data: Killik River.

Sample Results - Atigun Pass

Typical yields for the samples were very good (>20 dateable grains) and in most cases 20-25 grains were counted on each mount. Due to relatively young ages and, in some cases, low uranium content (<10 ppm) only 7 of 16 mounts contained 100 or more confined tracks. Five mounts had less than 20 confined tracks. Most samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations. For these samples the pooled fission track age is presented. The mean age is presented for those samples where it was determined that the dated grains did not represent a single age population.

Table 17. Apatite fission track analytical results: Ati un Pass.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

Sample Results - Dalton Highway

Typical yields for the samples were very good and in most cases at least 20 grains were counted on each mount. Due to relatively young ages and, in some cases, low uranium content (<10 ppm) only 4 of 17 mounts contained 100 or more confined tracks. Nine mounts had less than 50 confined tracks. Most samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations. For these samples the pooled fission track age is presented. The mean age is presented for the samples (shown by a * in Table 20) for which it was determined that the dated grains represented multiple populations.

Table 20. Apatite fission track analytical results: Dalton Highway.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

90TM494A	67°56.0'	150°07.3'	(1452)/(*4840*)	Kekiktuk Fm.	Mississippian	~323-362	Sandstone
90TM495B	67°57.8'	149°54.6'	(768)/(*2560*)	Kekiktuk Fm.	Mississippian	~323-362	Sandstone

Sample Results - Mt. Doonerak antiform

Typical yields for the samples were fair (>15 dateable grains) and in most cases at least 15 grains were counted on each mount. Due to very young fission track ages only 1 of 5 mounts contained 100 or more confined tracks. Two mounts had less than 20 confined tracks. Most samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations. For these samples the pooled fission track age is presented. The mean age is presented for 90TM491A because it was determined that the dated grains did not represent a single age population.

Table 23. Apatite fission track analytical results: Mt. Doonerak antiform.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

Sample Results - Arrigetch and Igikpak plutons

Typical yields for the samples were very good and in most cases 20 grains were counted on each mount. Due to relatively young ages and, in some cases, low uranium content (<10 ppm) only 4 of 14 mounts contained 100 or more confined tracks. Eleven mounts had less than 50 confined tracks. All samples passed the Chi-Squared test, thus the pooled fission track age is reported for each.

Table 26. Apatite fission track analytical results: Arrigetch and Igikpak plutons.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)

Sample Results - Chandalar plutons

Typical yields for the samples from Chandalar plutons were very good and in all but one case 20 dateable grains were found on each mount. Due to relatively young ages and in some cases, low uranium content (<10 ppm), only 7 of 13 mounts contained 100 or more confined tracks. Four mounts had less than 50 confined tracks. All but two samples passed the Chi-squared test, indicating that the dated grains from those samples represent statistically valid single populations.

Table 29. Apatite fission track analytical results: Chandalar plutons.

Sample Number	Number of grains	Standard track density ($x10^6 cm^{-2}$)	Fossil track density ($x10^5 cm^{-2}$)	Induced track density ($x10^6 cm^{-2}$)	Chi square probability (%)	Fission track age (Ma)	Uranium (ppm)	Mean track length (μm)	Standard deviation (μm)
