Overview of Environmental and Hydrogeologic Conditions at Tanana, Alaska

By Allan S. Nakanishi and Joseph M. Dorava

Abstract

The remote Native village of Tanana along the Yukon River in west-central Alaska has long cold winters and short summers. The Federal Aviation Administration owns or operates airway support facilities near Tanana and wishes to consider the subsistence lifestyle of the residents and the quality of the current environment when evaluating the severity of environmental contamination at these facilities. Tanana is located on the flood plain of the Yukon River and obtains its drinking water from a shallow aquifer located in thick alluvium underlying the village. Surface spills and disposal of hazardous materials combined with annual flooding of the Yukon River may affect the quality of the ground water. Alternative drinking-water sources are available, but may cost more than existing supplies.

INTRODUCTION

The Federal Aviation Administration (FAA) owns and (or) operates airway support, and navigational facilities throughout Alaska. At many of these sites, fuels and potentially hazardous materials such as solvents, polychlorinated biphenyls (PCB's), and pesticides may have been used and (or) disposed of. To determine if environmentally hazardous materials have been spilled or disposed of at the sites, the FAA is conducting environmental studies mandated under the Comprehensive Environmental Response, Compensation, and Liability Act (CERCLA or "Superfund Act") and the Resource Conservation and Recovery Act (RCRA). To complete these environmental studies, the FAA requires information on the hydrology and geology of areas surrounding the sites. This report is the product of a compilation, review, and summary of existing hydrologic and geologic data by the U.S. Geological Survey, in cooperation with the FAA, and provides such information for the FAA facility and nearby areas at Tanana, Alaska.

BACKGROUND

Location

Tanana (fig. 1) is located in the western interior of Alaska at latitude 65°10'00" N., longitude 152°04'00" W., approximately 350 km west of Fairbanks. Tanana is on the north bank of the Yukon River, approximately 5 km northwest from the mouth of the Tanana River. The FAA facilities are at the Tanana airport (fig. 2), which has a 1340-m gravel runway immediately north of the village (Campbell, 1985; U.S. Army Corps of Engineers, 1987).

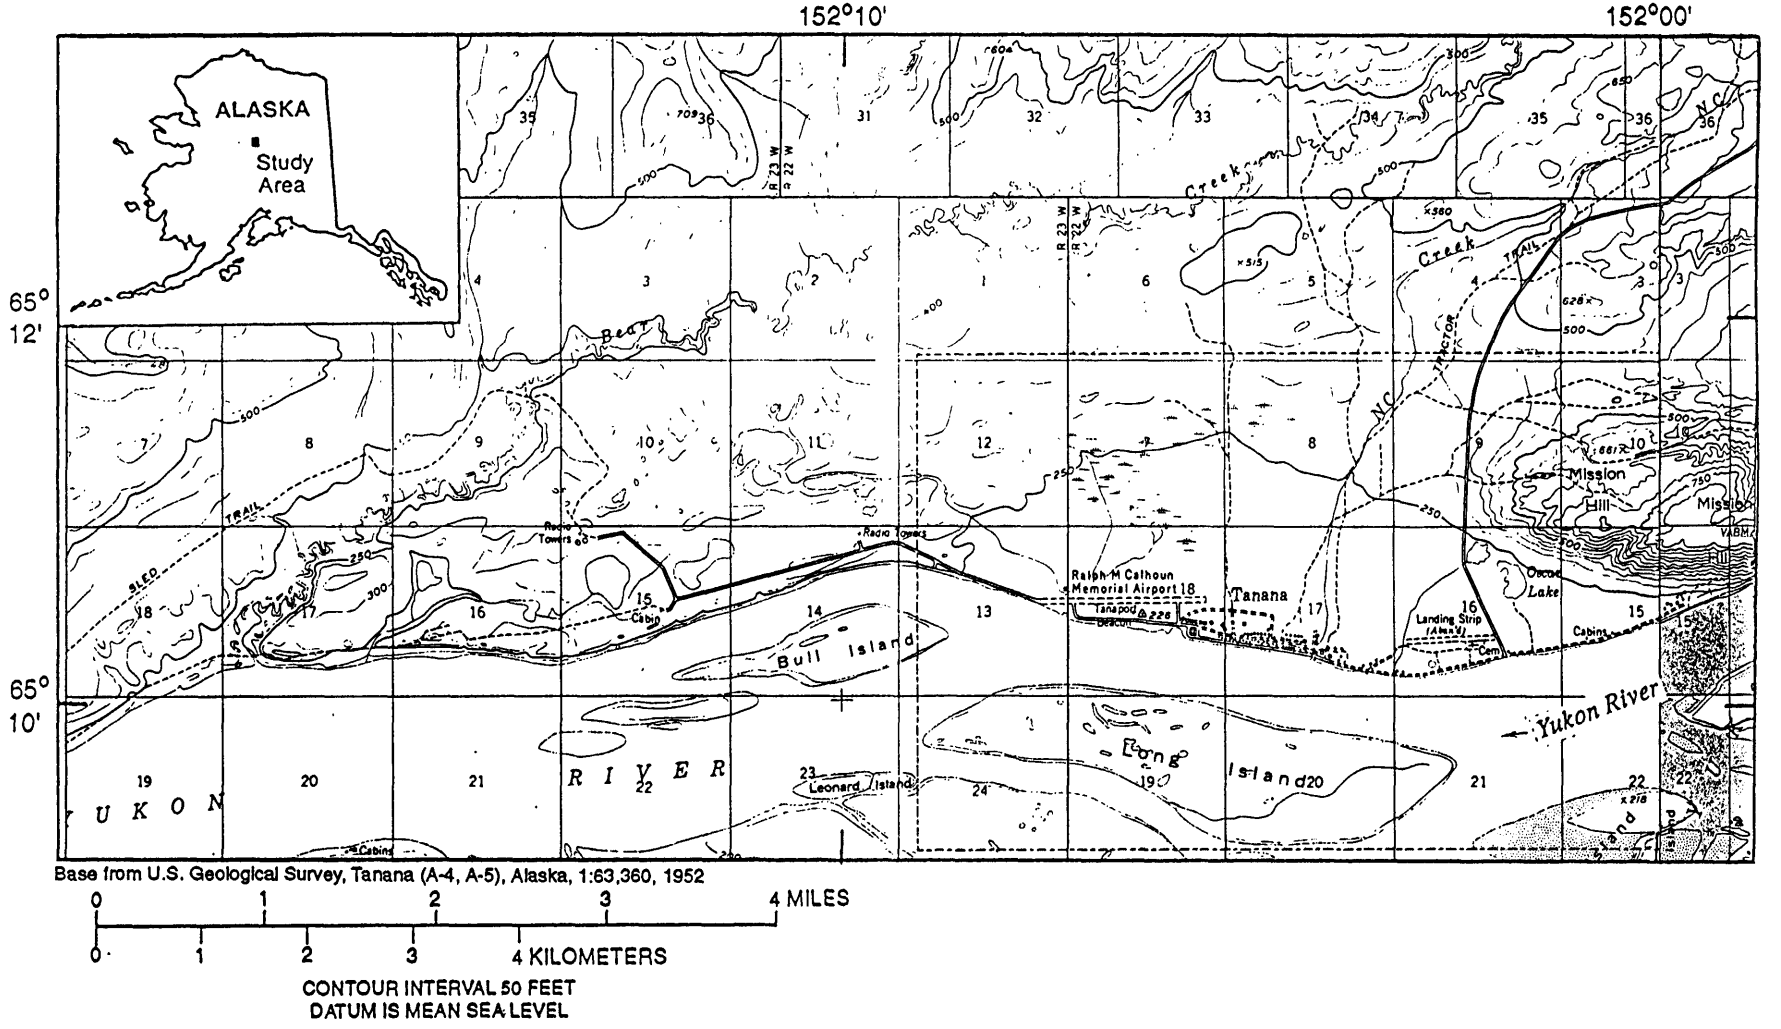

Figure 1. Location of Tanana.

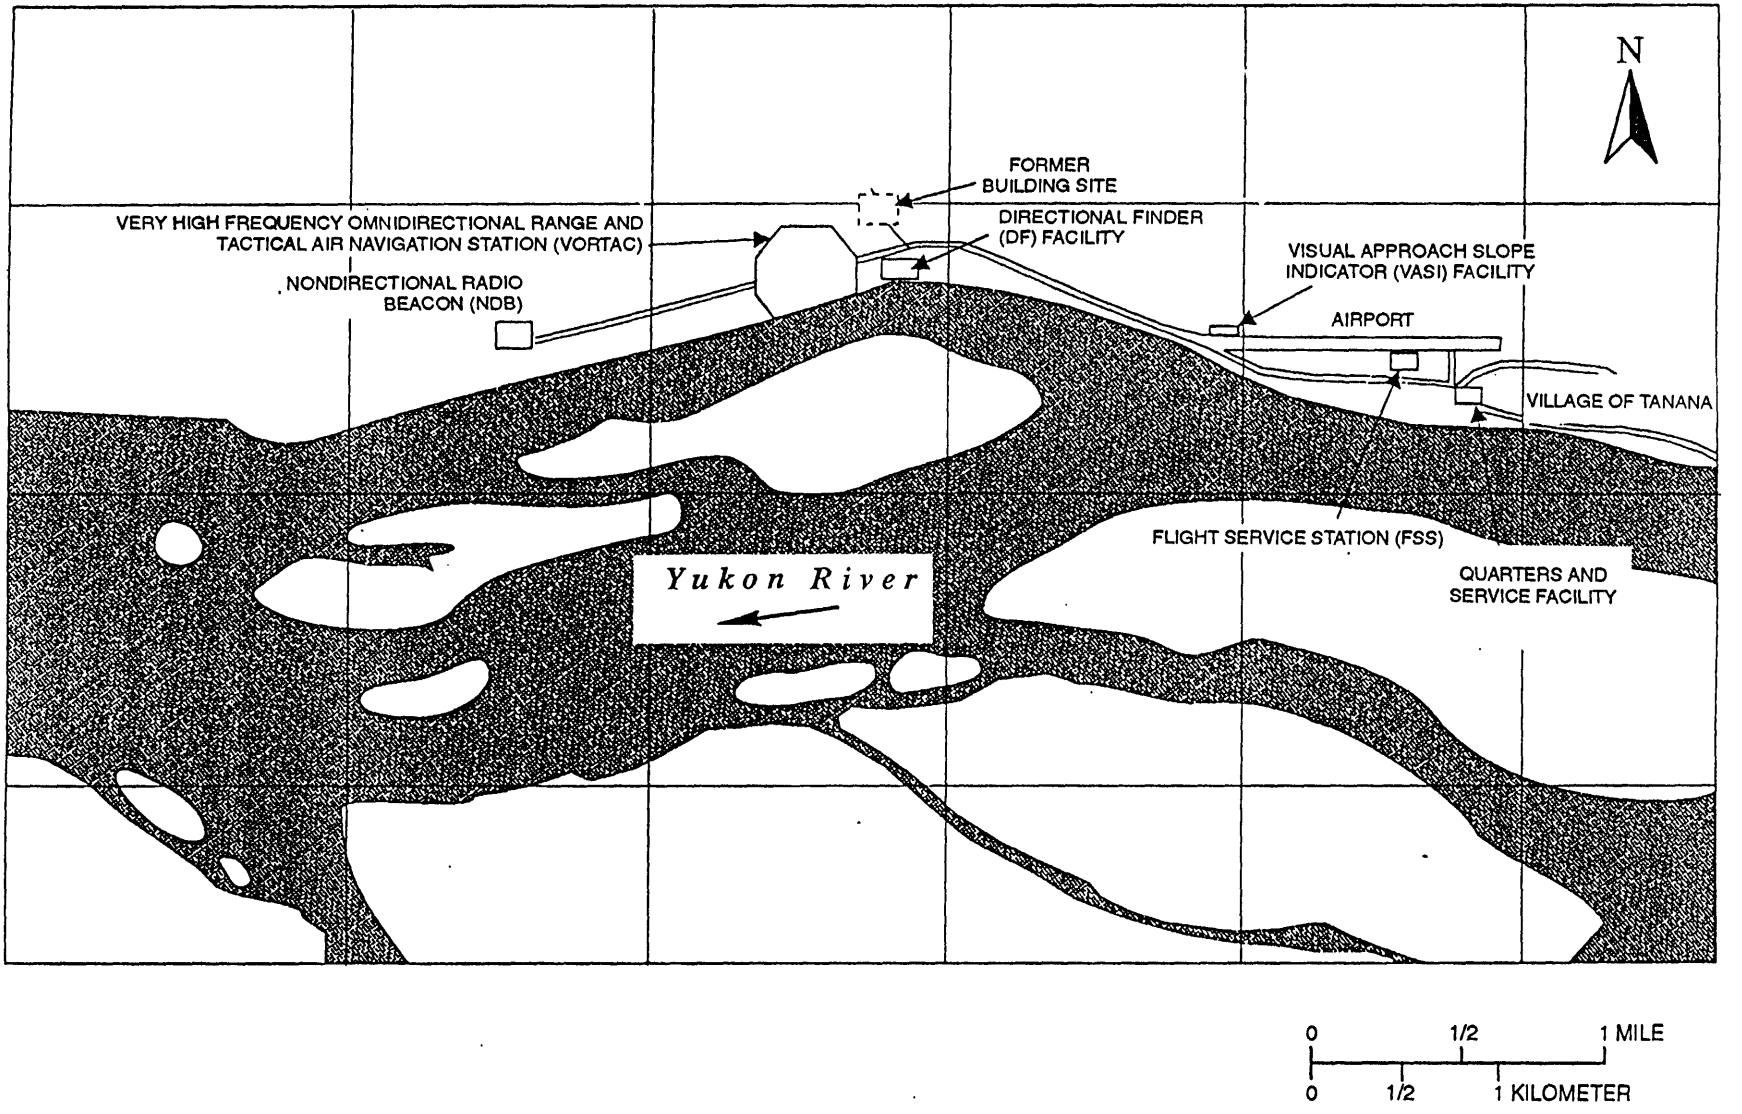

Figure 2. Location of Federal Aviation Administration (FAA) facilities near the village of Tanana (modified from Ecology and Environment Inc., 1992).

History and Socioeconomics

The area around Tanana was originally the territory of the Tanana and Koyukon Athabascan Indians who used semi-permanent sites along the Yukon River during the spring and summer to harvest fish and waterfowl (Campbell, 1985). During the mid-1800's, early European traders established Tanana as a trading outpost with the local Indians. The St. James Mission built a school and hospital complex between 1887 and 1900, which established Tanana as an important service and social contact center for area residents (Alaska Department of Community and Regional Affairs, 1993). The U.S. Army established Fort Gibbon in 1898 to maintain a telegraph line connecting Fairbanks to Nome (Campbell, 1985; Alaska Department of Community and Regional Affairs, 1993). The Tanana Hospital, which was in operation from the early 1940's to 1982, was for many years the only medical facility serving Interior Alaska. The activities of the regional hospital supported the expansion of the airport and FAA facilities, making Tanana an important air terminal and refueling stop (Campbell, 1985).

Tanana was incorporated as a first-class city in 1961. The village is managed by an elected mayor and a six-member council. According to the U.S. Bureau of Census (1991), the population of Tanana in 1990 was 345, of which 78 percent were American Indian, Eskimo, or Aleut. The Tanana economy is highly dependent on government spending and subsistence (Campbell, 1985; Fison and Associates, 1987). Many of the government jobs, however, are seasonal and part time. Trapping and commercial fishing also provide seasonal cash income.

PHYSICAL SETTING

Climate

Tanana is situated at the southwestern tip of the Rampart Trough physiographic province (Wahrhaftig, 1965). The area surrounding Tanana is described by Hartman and Johnson (1984) as having continental climatic conditions. Low precipitation, low cloudiness, low humidity, light surface winds, and great diurnal and annual temperature variations are typical. Freezing of the Yukon River typically occurs in early to mid-October and break-up occurs in mid-May (Fountain, 1984; Fountain and Vaughn, 1984). The mean annual temperature is -4.4 °C, but temperatures range from a July mean maximum of 21.3 °C to a January mean minimum of -27.4 °C. Mean annual precipitation is 336 mm; approximately 1,270 mm of snow falls annually (Leslie, 1989). Most rainfall occurs in July and August. Mean monthly temperature, precipitation, and snowfall are summarized for the periods 1922-76 and 1985-87 in table 1.

Vegetation

The Tanana area forest consists of a closed spruce-hardwood along the Yukon River (Viereck and Little, 1972). Well-drained, high-relief areas contain aspen, birch, poplar, and white spruce (Campbell, 1985; Hartman and Johnson, 1984). The flat, poorly drained areas away from the river consist predominantly of densely spaced black spruce, birch, and alder. The forest floor in both well and poorly drained areas has undergrowth that includes moss, sedge, alder, willow, wild rose, high and low bush cranberry, blueberry, Labrador tea and equisetum (Campbell, 1985). Poorly drained wet areas contain extensive growths of muskeg, sedges, tussock grasses, dwarf birch, and larch.

Bedrock Geology

The mountains and hills north of Tanana consist primarily of metamorphic and sedimentary rock. Sedimentary rock includes limestone, dolomite, greenstone, and chloritic schist of Paleozoic age (Chapman and others, 1982). Metamorphic rock includes quartz-mica schist, quartzite, slate, and phyllite which are early Paleozoic to Precambrian in age. Mission Hill, approximately 8 km west of the airport, is the closest bedrock exposure and is composed of conglomerate, sandstone, shale, siltstone and minor amounts of lignite of Tertiary age (Chapman and others, 1982). An early report by Mertie (1937) described the geomorphology, bedrock geology, and economic geology of the Yukon-Tanana Region. Drillers' logs for wells near Tanana indicate sandstone at an average depth of 15 m below land surface, and schist at approximately 19 m and 43 m depth below land surface (appendix 1).

Surficial Geology and Soils

The surficial deposits in the Tanana area are of Quaternary age and consist of alluvial, colluvial, and eolian deposits (Chapman and others, 1982). Alluvial deposits consist of sandy gravel and sandy silt with sub-rounded to well-rounded coarse-grained clasts. Alluvium was deposited in much of the flood plain of the Yukon River and its tributaries. Colluvial deposits are undifferentiated and consist predominantly of silt containing some poorly sorted sand and gravel. These deposits are found along valley sides and valley bottoms north of Tanana and border the alluvial deposits. Eolian loess consisting of well-sorted silt is found predominantly on the flood plain across the Yukon River, south of Tanana (Chapman and others, 1982).

Rieger and others (1979) described three basic types of soils in the Tanana area as poorly drained, well drained, and organic.

Poorly drained soils are found in low-lying areas such as meander scars on the flood plains. They have thick surface organic horizons composed primarily of sedges or sphagnum moss. The texture varies from silt-loam to sandy-loam. Poorly drained soils are usually saturated above a shallow permafrost table, but some are dry in the upper horizons in midsummer.

Well-drained soils are found on natural levees along existing and former river channels. The soil texture generally consists of stratified silt-loam and fine sand. Thin seams of organic material occur throughout the soil. Permafrost may occur at depths greater than 150 cm under these soils.

Organic soils are found on slightly lower areas of the flood plains than the poorly drained mineral soils. They consist of thick deposits of very acidic moss-peat in the upper layer and of fibrous sedge-peat in the lower layers. The soils are underlain by permafrost at depths of 12 to 75 cm.

HYDROLOGY

Surface Water

The Yukon River at Tanana flows roughly from east to west and drains into the Bering Sea about 1,110 km downstream from the village. The Yukon River is the largest drainage system in Alaska in terms of drainage basin area and mean annual flow. The two closest major drainages into the Yukon River are the northward flowing Tanana River and southward flowing Tozitna River, located 5 km upstream and 15 km downstream from Tanana, respectively.

Other than the Yukon River, the two local surface-water bodies closest to the village of Tanana are Bear and NC Creeks (fig. 1). Bear Creek flows southwestward into the Yukon River and drains the mountains and hills north and northwest of Tanana (fig. 1). NC Creek flows southward through the eastern part of Tanana into the Yukon River and drains the mountains and hills to the northeast of the village (fig. 1). The mouth of Bear Creek is located approximately 10 km from the village and the mouth of NC Creek is located at the east end of the village and on the north bank of the Yukon River. Streamflow data for both creeks are not available; however, mean annual flow estimates were calculated using Parks and Madison's (1985) equation for regional streamflow characteristics. This equation requires values of mean annual precipitation and drainage basin area. The drainage basin areas for Bear and NC Creeks, as measured from the USGS Tanana 1:250,000 quadrangle, are about 197 and 34 km^2, respectively. The mean annual precipitation of 510 mm was used to represent the precipitation for the drainage area of the creeks (Lamke, 1978). Mean annual streamflow estimates are 1.6 m^3/s for Bear Creek and 0.25 m^3/s for NC Creek.

Several small lakes (less than 0.65 km^2 in size) are near the mouth of the Bear Creek drainage and east of the village: the closest is about 2.5 km from the airport. Two small lakes, Oscar Lake and an unnamed lake are about 3.2 km west of the airport.

Floods

The U.S. Army Corps of Engineers (1993) recorded flooding at the village of Tanana in 1937, 1964, 1972, 1989, and 1991. The flood hazard in Tanana area is considered low by the U.S. Army Corps of Engineers (1993): approximately 50 houses are located within the 100-year flood zone. During the 1991 flood, one house was reported to have been inundated (U.S. Army Corps of Engineers, 1993). Because of the low flood hazards at Tanana, construction of flood-protection measures for the village have not been undertaken.

The primary cause of floods at Tanana is ice jams and subsequent stream overflow (U.S. Army Corps of Engineers, 1993). Ice-jam flooding occurs when river ice broken during spring thawing is transported downstream and its movement is blocked in locations where a constriction, a sandbar, or other obstruction such as a sharp meander bend exists (Beltaos, 1990). The blockage prevents ice movement and restricts water flow as the ice jam builds in thickness and length. This subsequently slows the water velocity and produces a rise in water level, or a backwater effect, that propagates upstream from the ice jam. When the ice jam releases, a flood wave propagates downstream.

Flooding at Tanana not only damages structures and roads, but can also cause contaminants on the surface of the land to mobilize and move into inadequately sealed wells. If flood waters are higher than the top of well casings, contaminants may move directly into drinking-water supplies.

The flood frequency for the Yukon River at Tanana (table 2) was obtained using the graph of discharge to drainage area (Jones and Fahl, 1994, fig. 10) for the Yukon River. The drainage area for the Yukon River basin upstream from Tanana is about 637,000 km^2. The frequency curves of Jones and Fahl (1994), however, apply only to floods generated by rainfall and snowmelt runoff and are not applicable to ice-jam floods.

Table 2. Estimated peak discharges of the Yukon River at Tanana for various recurrence intervals

[Discharge in cubic meters per second]

Recurrence interval						
2 years	5 years	10 years	25 years	50 years	100 years	500 years
16,000	20,000	23,000	25,000	27,000	29,000	33,000

Ground Water

Ground-water recharge to the Tanana area occurs from infiltration of precipitation, infiltration from streams, and normal ground-water movement from areas near the slopes of the surrounding highlands. Ground-water recharge most likely takes place from local streams such as Bear and NC Creeks and from the Yukon River. Recharge from the streams is assumed because the elevation of the stream bottom is most likely higher than the expected water table. Descriptions of ground water in permafrost regions by Cederstrom and others (1953), Hopkins and others (1955), and Williams and Waller (1963) include ground water of the Tanana area.

Tanana is located in a zone of discontinuous permafrost (Ferrians, 1965). Paths for ground-water flow are influenced by the presence of permafrost acting as an impermeable barrier. Alluvium is probably unfrozen beneath the bed of the Yukon River throughout its course in Alaska and is likely to be extensively, but not completely frozen, beneath the flood plain adjacent to the river. The hydraulic continuity of the unfrozen alluvium away from the river is expected to have a profound influence on the directions of ground-water flow. However, little information is available on the continuity of the permafrost in Tanana. If the permafrost in the area is discontinuous, the unconsolidated materials will behave like an aquifer, or if continuous, the permafrost will act as a confining layer. According to Smith (1986), most of the wells that supply the Yukon River villages from Canada to the Bering Sea are along the riverbank where the warming effect of the river affects the thickness of frozen ground.

Well-log and water-quality data are available from the U.S. Public Health Service for the years 1967-81 (appendix 1). Permafrost was recorded in logs of about three-fourths of the dry wells. The wells ranged in depth from 13 to 63 m and averaged approximately 28 m. Static water levels ranged from 4 to 12 m below land surface and averaged 7 m. Ground water appears to be produced consistently from a layer of sandy gravel that occurs at depths of 10 to 20 m below land surface. Bedrock, which was found in about one-third of the wells, was reached at depths from 11 to 43 m below land surface and at an average depth of 18 m. Well yields ranged from a low of 0.017 L/s to a high of 3.2 L/s, and averaged about 0.80 L/s.

Ground-Water and Surface-Water Interaction

The variations in river stage and ground-water elevations at Tanana will generally follow the pattern of the discharge hydrograph for the Yukon River at Ruby (fig. 3) located about 190 km downstream from Tanana. Continuous streamflow records are not available for the Yukon River at Tanana; however, a mean daily discharge record for the period 1956-78 is available for the Yukon River at Ruby (U.S. Geological Survey, 1957-79). The drainage basin area for the Yukon River at the village of Tanana is 637,000 km^2 and that for the Yukon River at the stream-gaging station at Ruby is 671,000 km^2. The difference in the drainage basin areas between these two sites is about five percent.

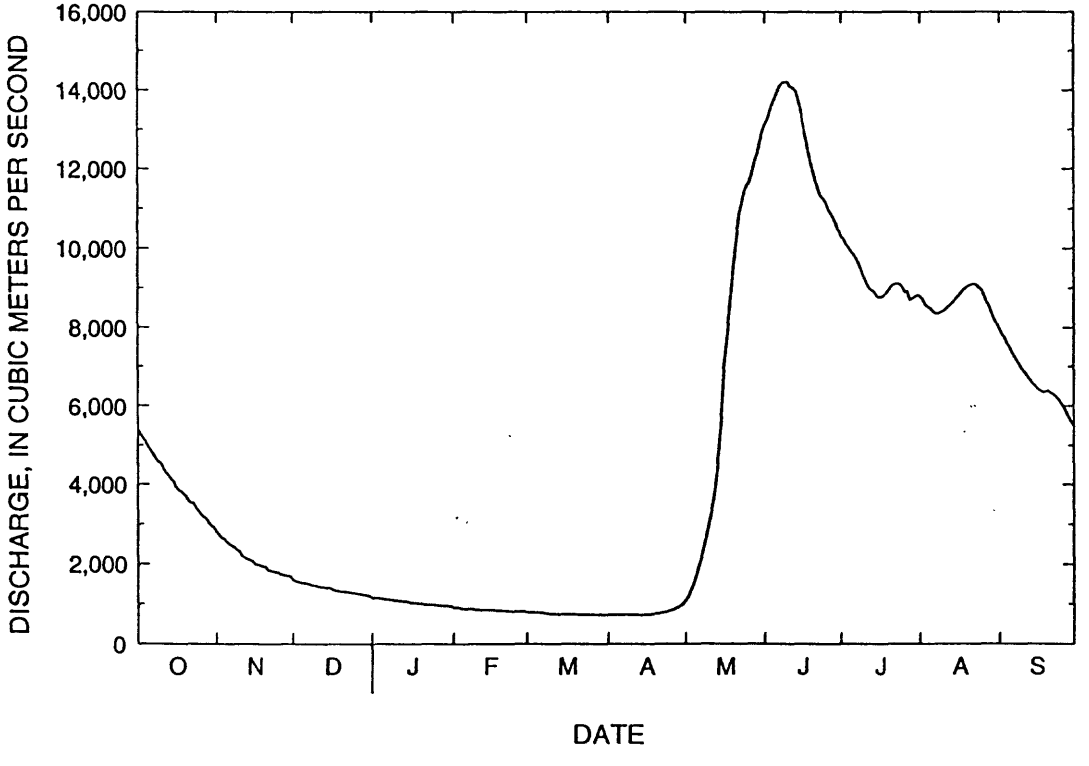

Figure 3. Mean daily discharge for the Yukon River at Ruby, water years 1966-76.

Adjacent to the river, shallow ground water can flow into and out of the riverbanks depending on the elevation of water of the river surface relative to the water table. Typically, the Yukon River will fluctuate from a maximum discharge in late May or early June to a minimum flow in late April or early May (fig. 3). The river also rises during late summer rainstorms. The water table will generally rise and fall in response to these river fluctuations, but will be attenuated with distance from the river. This flow of water into and out of the aquifer in response to changing stage of the river is termed "bank storage effects" (Linsley and others, 1982). Bank storage effects have not been studied at Tanana. Because the FAA facilities and village utilities are adjacent to the river, bank storage effects could have a significant influence on the ground-water flow beneath them.

Simulation of Ground-Water Movement

A mathematical ground-water model approximates the directions and rates of water movement through an aquifer system. Partial-differential equations thought to represent the physical processes of ground-water flow are solved by the model and requires that the hydraulic properties and boundaries be defined for the modeled area. The aquifer system was overlain by a grid, which was extended in the third dimension to form blocks or "cells." The cells form rows, columns, and layers. Each cell in the model grid represents a block of permeable material within which the hydraulic properties are assumed to be uniform. Any specific cell may be referenced by citing its row, column, and layer location. The limits of the modeled area were selected to include or nearly coincide with natural flow boundaries. The "boundary surface" of the flow region corresponds to identifiable hydrogeologic features at which some characteristic of ground-water flow can be described. For the conceptual model, these features could be a drainage divide, river bank, or artificially induced (depending on the modelled area). In cases where there is no apparent natural flow boundaries, such as in an open flood plain, the model grid was extended far enough away from the area of study so the error created from the artificial boundary is minimized.

Ground-water flow in the Tanana area was simulated using a computer program, MODFLOW (McDonald and Harbaugh, 1988), as a simple steady-state conceptual model. Under steady state conditions, the recharge to the system is equal to the discharge from the system, no water is derived from storage, and there is no change in head with time. Output from MODFLOW was graphically presented using METAZ, a contouring program specifically designed for MODFLOW and developed by S.A. Leake and R.T. Hanson (U.S. Geological Survey, written commun., 1993). The conceptual model requires that the hydraulic head at the aquifer boundaries is known, all recharge and discharge is assumed to occur at the river, flow is horizontal, and the aquifer materials are homogeneous and isotropic. The data, assumptions, justifications, and data sources used in the model packages are summarized in appendix 2. An example output file of the model is shown in appendix 3. The purpose of undergoing a mathematical ground-water simulation was to identify hydrologic features that may have a significant influence on the ground-water flow direction in the Tanana area. Two ground-water flow simulations were used to identify features having the greatest influence on ground-water flow direction.

The southern aquifer boundary was assumed to be the banks of the Yukon River. Elevations for the Yukon River were established from the USGS 1:63,360 scale Tanana A-4 and A-5 topographic maps. The contact between the alluvial aquifer and the bedrock hills was estimated to be the 250-foot topographic contour line taken from the Tanana A-5 quadrangle and this contour line was modeled as the northern aquifer boundary. The ground-water flow simulations assume that

permafrost is not a barrier to flow in the Tanana area. Potentially significant hydrologic features, such as Bear and NC Creeks (fig. 1), were included in the ground-water model to determine their effects on the ground-water flow in the area.

Simulated ground-water flow in the Tanana area is generally towards the southwest (fig. 4). Two simulations were done assuming low and high streambed conductances for the local creeks. The degree of influence of Bear and NC Creeks on ground-water flow is dependent on the streambeds' vertical hydraulic conductances. In general, an increase in conductance increases the rate of flow between the streambed and the aquifer. The effect of the creeks becomes apparent in the highest streambed conductance model run where ground-water flow direction changes from a southwestward (fig. 4) to a nearly southward direction (fig. 5).

The simulations, each using different assumptions of the conductance of the streambed, illustrate the importance of the hydraulic connection between Bear and NC Creeks and the aquifer. Further investigation of the extent of permafrost in the Tanana area is necessary to establish its influence on ground-water flow. Without these field data, shallow ground-water flow directions can not be ascertained exactly, but can be described only generally on the basis of assumed boundary conditions.

DRINKING WATER

Present Drinking-Water Supplies

The village of Tanana obtains its drinking-water supply from ground water using both public and private wells. The Alaska Department of Community and Regional Affairs database (1993) indicates that 109 households use the village-managed public water system, 22 households use individual wells, and another 33 households use unspecified water sources. A community watering point (washeteria) is supplied by two wells, one active and one backup. The community water is softened to reduce iron content, fluoridated, chlorinated, and then stored in holding tanks in the village-maintained washeteria building. Water quantity provided by the community wells fluctuates with seasonal changes and is lowest during the spring months (Fison and Associates, 1987; Campbell, 1985). The village of Tanana operates a water truck that delivers water to homes equipped with water storage tanks. Residents who do not have water delivered regularly haul drinking water from the washeteria (Campbell, 1985).

The Tanana village school, health center, elderly center, council building, and teacher housing are supplied by a 47-m deep well drilled in 1976 (appendix 1). This water is chlorinated, fluoridated, and stored in three 76,000-liter storage tanks (Fison and Associates, 1987).

The FAA owns four wells, of which three are active. One of the wells, about 15 m deep, is used for drinking water and serves the flight service station and FAA housing (Fison and Associates, 1987; Ecology and Environment Inc., 1993). The second active well is used to supply water to a flush toilet and the third active well is used as a standby source of drinking water (Ecology and Environment Inc., 1993).

The average per capita water use for the village of Tanana is estimated to be 150 L/d for self-supplied water and 300 L/d for public-supplied water (Solley and others, 1993). The average water use per person for all uses for the entire State of Alaska in 1990 is estimated to be 1,950 L/d.

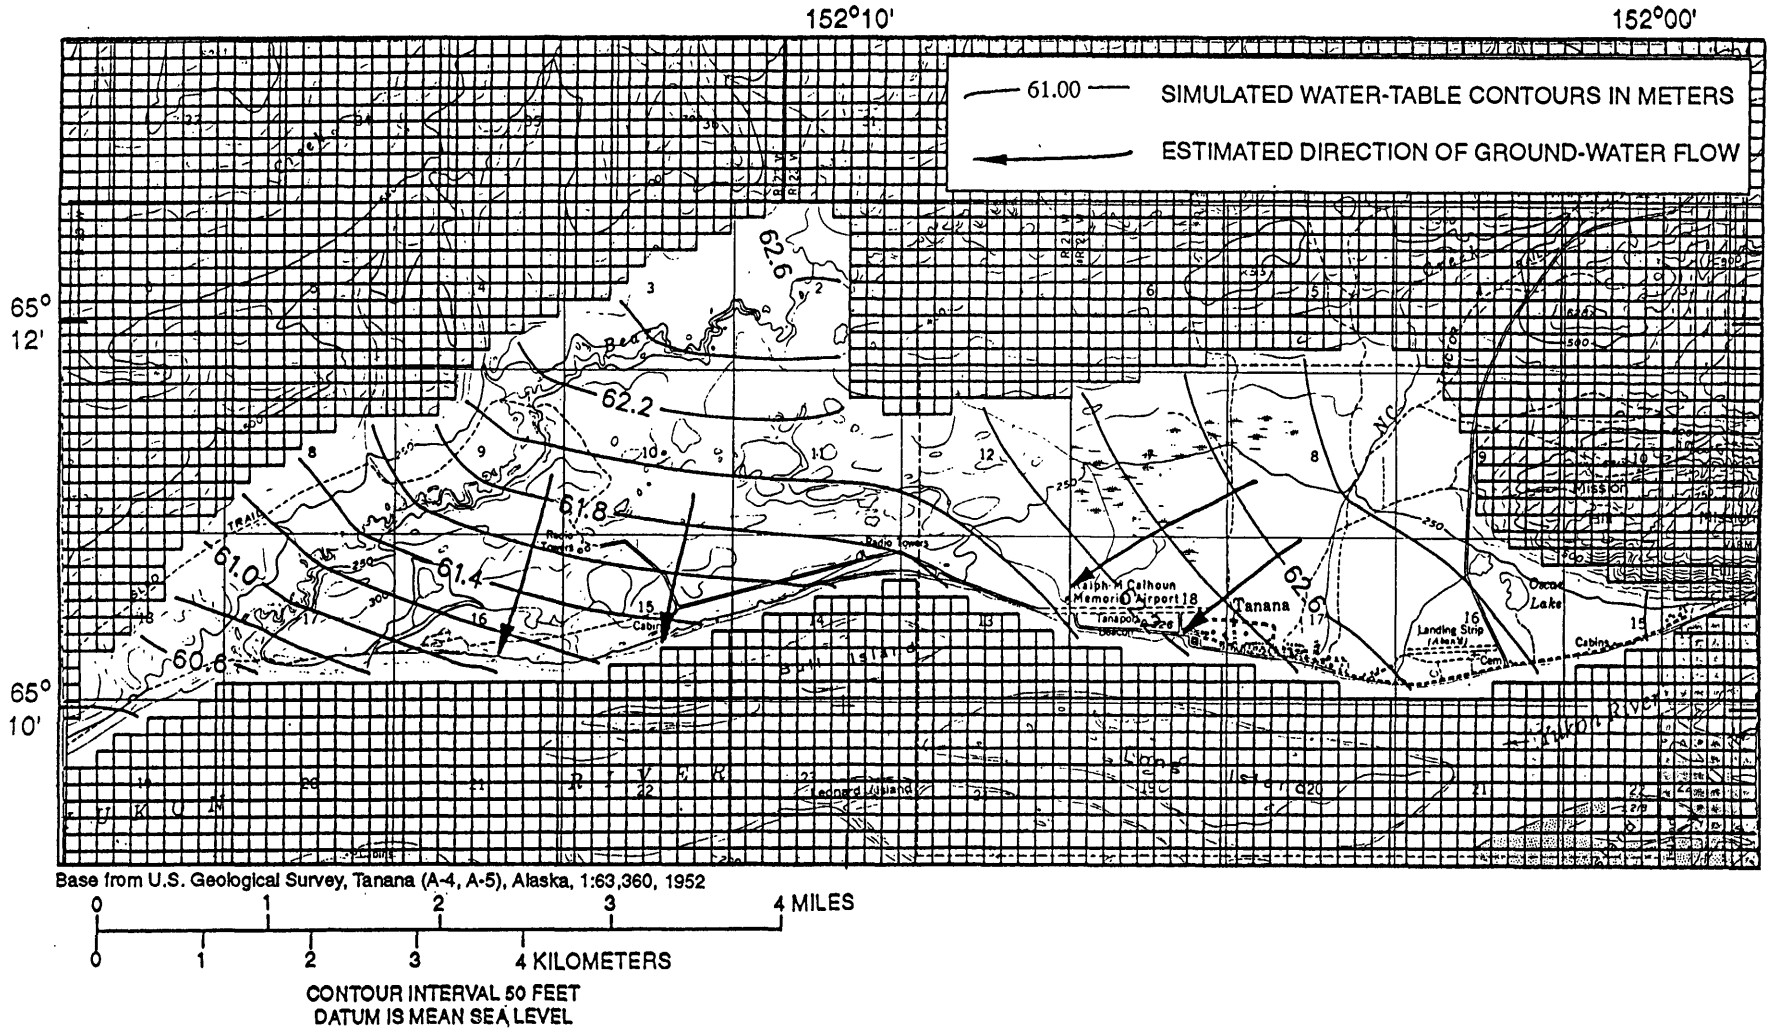

Figure 4. Simulated water-table contours and estimated flow direction of shallow ground water with low streambed conductance in the Tanana area.

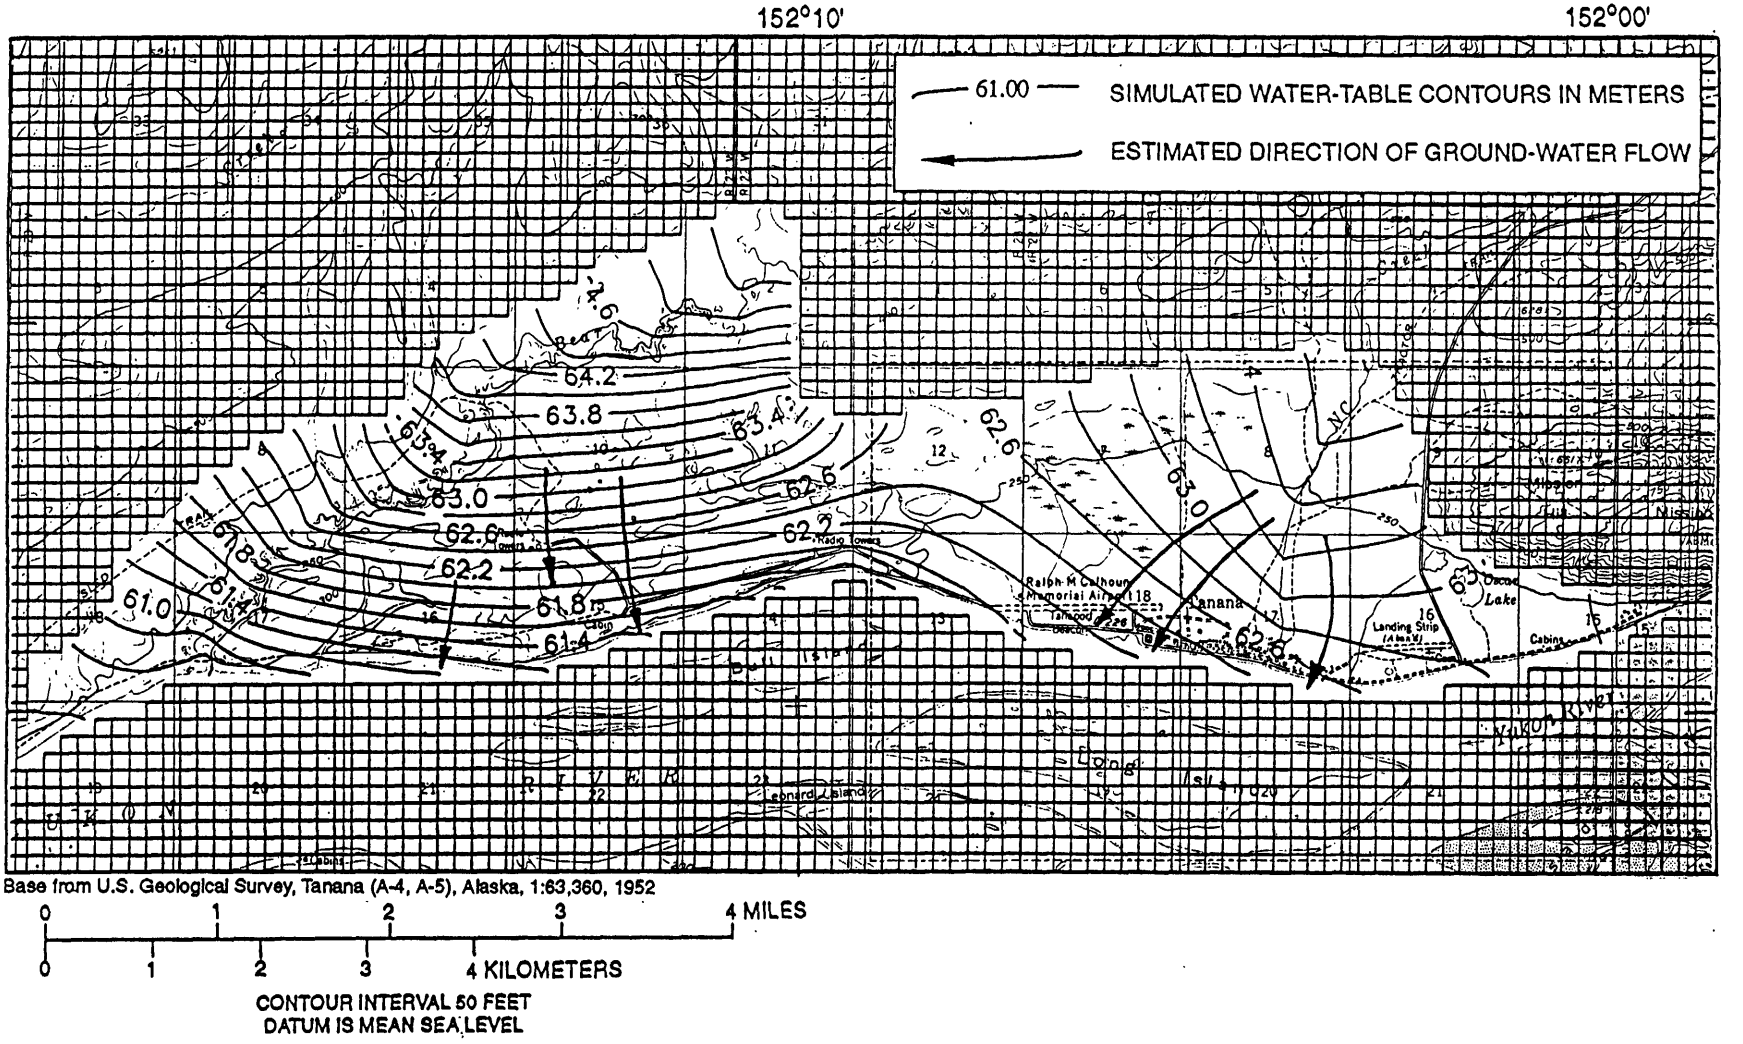

Figure 5. Simulated water-table contours and estimated flow direction of shallow ground water with high streambed conductance in the Tanana area.

Quality of Present Supplies

Permafrost commonly has a strong influence on the water quality in an area. Shallow aquifers above the permafrost (suprapermafrost aquifers) are generally susceptible to surface contamination. The quantity of water from this source is often low and unreliable. Ground water found below permafrost (subpermafrost aquifers) is generally deficient in dissolved oxygen. As a result, high concentrations of some minerals, such as iron and manganese, which are soluble under these conditions, are present. Subpermafrost ground water is commonly hard and occasionally contains dissolved organic substances (Williams, 1970).

Sporadically kept records on the water quality in the Tanana area are available from the U.S. Public Health Service for the period 1973-80 (appendix 1) and from the USGS for the period 1955-73 (appendix 4). Analyses of untreated samples taken from various locations in Tanana indicate an average silica content of 11 mg/L, an average hardness as $CaCO_3$ of 283 mg/L, and an average iron content of 1.6 mg/L (appendixes 1 and 4). Silica and hardness may create scale in plumbing and boilers but is of little health concern to most users. The average iron content is higher than the 0.30 mg/L secondary maximum contaminant level (SMCL) regulations set by the U.S. Environmental Protection Agency (USEPA) (1993) for drinking water, but does not prohibit this water from being used for drinking.

The drinking water at the FAA station was sampled regularly as a part of the Alaska Department of Environmental Conservation monitoring program. This monitoring program only required the testing for total coliform bacteria, and the tests consistently indicated satisfactory water quality for the Tanana FAA station (Ecology and Environment Inc., 1993).

Alternative Drinking-Water Sources

The FAA has requested information on alternative drinking-water sources in the Tanana area in order to plan actions that would be taken if the present drinking-water source became contaminated. Alternative drinking-water sources to be considered include nearby surface-water sources or aquifers that are separated from the present water-supply aquifer by a tight confining layer. It is possible that a continuous permafrost layer would act as a confining layer. However, the areal continuity of the permafrost is uncertain and it may or may not inhibit movement of contaminants to the subpermafrost aquifer. On the basis of well drillers' logs (appendix 1), it is unlikely that a separate aquifer system exists at the Tanana village site. The Yukon River is a possible water source for Tanana. Potential development and maintenance cost of a surface-water distribution system make the Yukon River less feasible as a water source (Smith, 1986).

Quality of Alternative Sources

Water quality of Arctic rivers can vary with the season and is generally excellent in the winter and poor in the summer (Smith, 1986). Streamflows are much greater in the summer than in winter and water from the river contains higher sediment concentrations from melting glaciers during the summer (Smith, 1986). Water from the Yukon River in winter is usually clear and free of sediment (Campbell, 1985). Because of the sediment concentrations during the summer, however, Yukon River water would require treatment. A treatment system would likely be more expensive to operate and maintain than the current system.

Water-quality information for the Yukon River is not available for the Yukon River at Tanana; however, water quality data are available for the Yukon River at Ruby. The water quality for the Yukon River at Ruby should closely reflect the water quality upstream on the Yukon River at Tanana. An analysis of sample data for all of the periods of record shows that iron concentration is typically below the USEPA's SMCL of 0.30 mg/L, but concentrations of 1.86 mg/L were recorded on July 9, 1967 (appendix 5). Maximum and minimum sediment concentrations have been 867 mg/L and 2 mg/L, respectively (appendix 5), and correlate closely with maximum and minimum river flow.

SUMMARY

Tanana serves as an important transportation, service and commercial center for the western interior of Alaska. Its remote location and lack of road access make it dependent on the airport or the river for transportation. The subsistence lifestyle of the Native residents makes them dependent on a sustainable environment. The community obtains drinking water from both village-maintained and private ground-water wells. The ground-water flow is strongly influenced by the Yukon River, by local streams, and by the continuity of permafrost in the area. The Yukon River could be an alternative drinking-water supply, but costs have not been estimated for the community to utilize this source.

CONTENTS:

PROJECT HISTORY

The existing well source for the PHS Hospital in Tanana was contaminated by an oil spill in late 1974. As a result, OEH was approached by the Hospital's Construction and Maintenance Branch to drill a new source. An agreement was reached, and the sum of $9000.00 was transfered to OEH control.

A PHS drill rig in Koyukuk had been leased to the state over the winter. Part of the lease agreement entitled PHS to have the state barge the drilling equipment to Tanana, free of charge to PHS. The drilling equipment arrived in Tanana in July 1976.

Charlie Bordner and Henry Horner drilled the new well in August. The well was drilled to a depth of 155 feet, as it was felt that the water bearing formation was somewhat shallow. As no water was hit, the casing was pulled back to 97 feet. The remainder of the hole was filled with cuttings.

COST SUMMARY FOR EXPENSES

ASSOCIATED W/WELL DRILLING

IN THE VILLAGE OF Tanana

I. Drilling manhours costs; includes drilling, bailing, driving casing, setting screens, development, setting pumps, test pumping, abandonement, fishing tools.	DRILLING MH COST	$ 2,520
2. Other manhour costs; includes travel time, standby time, site preparation, rig repair, loading and unloading equipment	OTHER MH COST	$ 4,247
3.	TOTAL MH COST	$ 6,767
4. Travel expense; includes expenses associated with transportation of drilling crews.	TRAVEL EXPENSE	$ 338
5. Cost to move rig; includes transporation costs for moving major well drilling items only	COST TO MOVE RIG	$ 376
6. Supply purchases; purchase of all well supplies including transportation	SUPPLY PURCHASES	$ 4,234
7.	TOTAL COSTS	$ 11,715*
8. #Wells/Total FT		1/155
9. Drilling Labor Cost/Ft		$ 16.00
IO. Total Cost/Ft		$ 76.00

*Of this amount $2,250 was charged to McGrath.

TO: BILL MACE

SUBJ: TANANA WELL LOCATIONS

DUE TO THE FAIRLY CONSISTENT SANDY GRAVELS AT DEPTHS RANGING FROM 35' to 65' AND relatively discontinuous permafrost — probability of subsurface water is just as good IN ONE PLACE AS ANOTHER WITHIN THE proposed subdivision.

POSSABILITY OF FROZEN GROUND MAY EXIST ~~may exist~~ DOWN TO BEDROCK WHERE WATER, IF ANY, WILL ONLY BE AVAILABLE IN FISSURES WITH FAIRLY LOW YIELD.

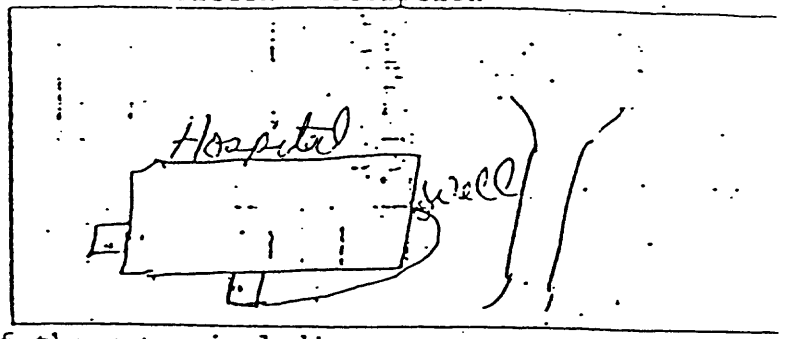
Sample # _____

Village of Tanana AK

Special Information See directions on back side.

1. Specify the exact sample location so there is no confusion about where the sample was collected. Include a written description and a map or sketch.

Tanana Hospital
Well



2. Describe the physical appearance of the water including:

Color Clear

Taste flat

Odor no odor

Turbidity _____

3. Describe the area immediately surrounding the sample site including nearby honey bucket dumps, oil storage areas, landfills. ect.

none above

4. Label each sample to include:

Name of Collector Ruth A. Grant

Time and date of collection 1:00 pm on NOV 28-79

Date sample mailed NOV-28-79

Water temperature _____

Sample depths/distance from shore (for surface sources) _____

Tidal influence (if any) _____

Approximate flow rate _____

Depth of well _____

Pumping rate and drawdown of well _____

pH _____

FOLD — INITIAL MESSAGE — FOL

The laboratory technician at the Tanana Hospital indicated that the crystaline material in frozen water looked milky. The above sample was supposed to have been taken from the ice machine so it may have the crystals in the sample.

REPLY MESSAGE

We could not notice any crystals or precipitate in the water sample when it was received. We suspected the crystaline material was carbonate so had the sample analyzed for Ca, Mg, pH, & alkalinity. However, the results were lower (except pH) than those of previous work. If the sample was of melted ice, it then explained the difference. However, if you could collect some crystals, (maybe water by filtration, & then place the crystals on a filter paper, white paper towel, etc) add a drop of vinegar to see if it would bubble and dissolve. If not, please send the dry crystal to me for identification.

APPENDIX 2

Data, assumptions, justifications, and data sources used in the MODFLOW packages

Ground-water flow at Tanana, Alaska - Modflow Notes

BAS Package

Packages Used: BAS, BCF, OC, SIP, RCH, RIV, STR

Single-layer model

Grid size:100 columns x 50 rows

IBOUND: All cells south of RIV nodes set at no-flow (0)

no-flow above the 250-ft contour (0), estimated limites of the aquifer

all other cells set at variable head (1)

Anisotropy: 1.00

BCF Package

Layer thickness: 100 ft (layer bottom is 100 ft above MSL)

DELR: 528 ft (0.1 mile)

DELC: 528 ft

Hydraulic Conductivity (K) along Rows: 80 ft/day, constant for all cells

RCH Package

Net annual recharge (recharge minus evapotranspiraton): 0.2300E-03 ft/day (1 inch/year)

RIV Package

River Reaches: 99

Yukon River

Slope: 0.000183, estimated from USGS Tanana A-4 and A-5, 1:63,360 scale maps.

Highest River Stage:207.2 ft, estimated from USGS Tanana A-4 and A-5, 1:63,360 scale maps.

River Conductance: 5.600E+06 ft^2/day (K = 20 ft/day = 7.1E-03 cm/s), estimated

Reach Length (L): 528 ft, unit cell size

Reach Width (W): 528 ft, unit cell size

Reach riverbed depth (D):1 ft, estimated

Conductivity Equation: (LW/D)K

Bottom elevation is estimated to be 50 ft lower than river stage height, estimated

STR Package

Total Stream Reaches: 67
Total Stream Segments: 2

Bear Creek
Southward flowing
Stream Reaches: 48
Stream Segments: 1
Streambed Conductance:
- low streambed conductance model value: 1.0E03 ft^2/day
- high steambed conductance model value: 5.0E03 ft^2/day
Reach Length (L):528 ft, unit cell size
Reach Width (W): 10 ft, estimated
Reach streambed depth (D): 0.5 ft, estimated
Conductivity Equation: (LW/D)K
Slope of stream was estimated from 1" to mile USGS topo elevation conturs: 0.002735
Lowest point of stream: at confluence with Yukon R. (r38,c12), 198.8 ft
Stream bed thickness: 0.5 ft (assumed)
Stream bed bottom elevation: 0.5 ft below streambed top elevation
Streambed top elevation:3 ft below stream stage
Streambed conductance: variable, influences magnitude of the stream effects on groundwater flow.

NC Creek
Southward flowing
Stream Reaches: 19
Stream Segments: 1
Streambed Conductance:
- low streambed conductance model value: 1.5E02 ft^2/day
- high steambed conductance model value: 1.5E04 ft^2/day
Reach Length (L): 528 ft
Reach Width (W): 5 ft
Reach streambed depth (D): 0.5 ft
Conductivity Equation: (LW/D)K
Slope of stream, estimated from USGS Tanana A-4 and A-5, 1:63,360 scale maps
seg.1-3: 0.0237
seg. 4-8: 0.0186
seg. 9-19: 0.00778
Stream bed thickness: 0.5 ft estimated
Stream bed bottom elevation: 0.5 ft below streambed top elevation, estimated
Streambed top elevation:3 ft below stream stage, estimated

MODEL TIME UNIT IS DAYS

I/O UNITS:
ELEMENT OF IUNIT:  1  2  3  4  5  6  7  8  9 10 11 12 13 14 15 16 17 18 19 20 21 22 23 24
        I/O UNIT: 31  0  0 34  0  0  0 38 39  0  0 42  0  0  0  0  0 35  0  0  0  0  0  0

BAS1 -- BASIC MODEL PACKAGE, VERSION 1, 9/1/87 INPUT READ FROM UNIT  5
ARRAYS RHS AND BUFF WILL SHARE MEMORY.
START HEAD WILL BE SAVED
    45154 ELEMENTS IN X ARRAY ARE USED BY BAS
    45154 ELEMENTS OF X ARRAY USED OUT OF   350000

BCF2 -- BLOCK-CENTERED FLOW PACKAGE, VERSION 2, 7/1/91 INPUT READ FROM UNIT 31
STEADY-STATE SIMULATION
CELL-BY-CELL FLOWS WILL BE RECORDED ON UNIT 21
HEAD AT CELLS THAT CONVERT TO DRY=  0.00000E+00
WETTING CAPABILITY IS NOT ACTIVE
      LAYER  AQUIFER TYPE
      -------------------
         1         1
    10001 ELEMENTS IN X ARRAY ARE USED BY BCF
    55155 ELEMENTS OF X ARRAY USED OUT OF   350000

RCH1 -- RECHARGE PACKAGE, VERSION 1, 9/1/87 INPUT READ FROM UNIT 38
OPTION 1 -- RECHARGE TO TOP LAYER
CELL-BY-CELL FLOW TERMS WILL BE RECORDED ON UNIT 21
     5000 ELEMENTS OF X ARRAY USED FOR RECHARGE
    60155 ELEMENTS OF X ARRAY USED OUT OF   350000

RIV1 -- RIVER PACKAGE, VERSION 1, 9/1/87 INPUT READ FROM UNIT 34
MAXIMUM OF    99 RIVER NODES
CELL-BY-CELL FLOWS WILL BE RECORDED ON UNIT 21
      594 ELEMENTS IN X ARRAY ARE USED FOR RIVERS
    60749 ELEMENTS OF X ARRAY USED OUT OF   350000

SIP1 -- STRONGLY IMPLICIT PROCEDURE SOLUTION PACKAGE, VERSION 1, 9/1/87 INPUT READ FROM UNIT 39
MAXIMUM OF  50 ITERATIONS ALLOWED FOR CLOSURE
 5 ITERATION PARAMETERS
    20205 ELEMENTS IN X ARRAY ARE USED BY SIP
    80954 ELEMENTS OF X ARRAY USED OUT OF   350000

STRM -- STREAM PACKAGE, VERSION 2, 12/18/90 INPUT READ FROM UNIT 35
MAXIMUM OF   67 STREAM NODES

NUMBER OF STREAM SEGMENTS IS      2

NUMBER OF STREAM TRIBUTARIES IS      ?

STREAM STAGES WILL BE CALCULATED USING A CONSTANT OF**********
     1082 ELEMENTS IN X ARRAY ARE USED FOR STREAMS
    82036 ELEMENTS OF X ARRAY USED OUT OF 350000

TWO DIMENSIONAL MODEL OF GROUND-WATER FLOW AT TANANA                                    1 layer, 50 rows, 100 columns, 0.1 mile grid

                                   BOUNDARY ARRAY FOR LAYER  1 WILL BE READ ON UNIT 61 USING FORMAT:  (10012)
                            ------------------------------------------------------------------------------------------------

            1          2          3          4          5          6          7          8          9         10
           11         12         13         14         15         16         17         18         19         20
           21         22         23         24         25         26         27         28         29         30
           31         32         33         34         35         36         37         38         39         40
           41         42         43         44         45         46         47         48         49         50
           51         52         53         54         55         56         57         58         59         60
           61         62         63         ..         65         66         67         68         69         70
           71         72         73         74         75         76         77         78         79         80
           81         82         83         84         85         86         87         88         89         90
           91         92         93         94         95         96         97         98         99        100

APPENDIX 4

U.S. Geological Survey ground-water quality data for Tanana, Alaska

U.S. DEPARTMENT OF THE INTERIOR
GEOLOGICAL SURVEY

WATER RESOURCES DIVISION

Analyses by Geological Survey, United States Department of the Interior

9-268 q (parts per million)

Laboratory Number	13257
Date of collection	Not given
Silica (SiO_2)	12
Iron (Fe) (total-approx.)	2.3
Manganese (Mn)	0.20
Manganese (Mn)	
Calcium (Ca)	61
Magnesium (Mg)	27
Sodium (Na)	9.1
Potassium (K)	1.6
Bicarbonate (HCO_3)	285
Carbonate (CO_3)	00
Sulfate (SO_4)	24
Chloride (Cl)	20
Fluoride (F)	1.5
Nitrate (NO_3)	1.1
Phosphate (P04) Total	0.0
Dissolved solids Calculated	300
Residue on evaporation at 180°C	
Hardness as $CaCO_3$	263
Noncarbonate hardness as $CaCO_3$	29
Alkalinity as $CaCO_3$	234
ABS	0.0
Specific conductance (micromhos at 25°C)	509
pH	7.7
Color	-

13257 - Tanana Hospital (Raw water). NOTE: Mr. Black. Comment: Nothing was found on this water sample that would cause foaming.

15-5648. YUKON RIVER AT RUBY
(International Hydrologic Decade Station)

LOCATION.--Lat 64°44'28", long 155°29'22", at gaging station on left bank at Ruby, 300 ft downstream from Ruby Creek, 1.5 miles downstream from Melozitna River, and 2.2 miles upstream from Ruby Slough.
DRAINAGE AREA.--259,000 sq mi, approximately.
PERIOD OF RECORD.--Chemical analyses: June 1966 to September 1969.
Water temperatures: June 1966 to September 1967, August to September 1969.
Sediment records: September 1967 to September 1969 (partial-record station).
EXTREMES, 1968-69.--Dissolved solids: Minimum, 109 mg/l June 8-19.
Hardness: Minimum, 92 mg/l June 8-19.
Specific conductance: Minimum daily, 185 micromhos June 7.
EXTREMES, 1966-69.--Dissolved solids (1967-69): Minimum, 95 mg/l June 3-17, 1968.
Hardness (1967-69): Minimum, 81 mg/l June 13-17, 1968.
Specific conductance (1967-69): Minimum daily, 154 micromhos June 16, 1968.
Water temperatures (1966-67): Maximum, 18°C July 24, 26, 1966, June 24, July 11, 13, 1967.
REMARKS.--Stream frozen over during period October to May.

15564800 YUKON RIVER AT RUBY
(International Hydrological Decade River Station)

LOCATION.--Lat 64°44'28", long 155°29'22", at gaging station on left bank at Ruby, 300 ft downstream from Ruby Creek, 1.5 miles downstream from Melozitna River, and 2.5 miles upstream from Ruby Slough.

DRAINAGE AREA.--259,000 sq mi, approximately.

PERIOD OF RECORD.--Chemical analyses: June 1966 to September 1970.
Water temperatures: June 1966 to September 1967, August 1969 to September 1970.
Sediment records: September 1967 to September 1970 (partial-record station).

EXTREMES, 1969-70.--Dissolved solids: Maximum, 169 mg/l Mar. 8; minimum, 92 mg/l June 12.
Hardness: Maximum, 140 mg/l Mar. 8; minimum, 80 mg/l June 12.
Specific conductance: Maximum, 280 micromhos Mar. 8; minimum daily, 161 micromhos June 12.
Water temperatures: Maximum, 18°C July 1, 2, 4-6.

EXTREMES, 1966-70: Dissolved solids (1967-70): Maximum, 169 mg/l Mar. 8, 1970; minimum, 87 mg/l May 22-31, 1967.
Hardness (1967-70): Maximum, 140 mg/l Mar. 8, 1970; minimum, 75 mg/l May 22-31, 1967.
Specific conductance (1967-70): Maximum, 315 micromhos Aug. 1-16, 1967; minimum, 154 micromhos May 22-31, 1967.
Water temperatures (1966, 1967, 1970): Maximum, 18°C July 24, 26, 1966, June 24, July 11, 13, 1967, July 1, 2, 4-6, 1970.

REMARKS.--River frozen over during period October to May. Miscellaneous chemical data published for water years 1967-70 and sediment data for water years 1967-70.
