**STATUS OF GROUND-WATER RESOURCES AT  
U.S. NAVY SUPPORT FACILITY, DIEGO GARCIA:  
SUMMARY OF HYDROLOGIC AND CLIMATIC DATA,  
JANUARY 1992 THROUGH SEPTEMBER 1994**

**EXECUTIVE SUMMARY**

This report contains hydrologic and climatic data that describe the status of ground-water resources at U.S. Navy Support Facility, Diego Garcia. Data are presented from January 1992 through September 1994. This report concentrates on data from July through September 1994, and references historic data from 1992 through June 1994.

1. RAINFALL--Total rainfall for the first nine months of 1994 was about 77 inches which is 72 percent of the mean annual rainfall of 106 inches. In comparison, total rainfall for the first nine months of 1992 and 1993 was 67 inches and 69 inches, respectively. Annual rainfall totals in 1992 and 1993 were 93 inches and 95 inches, respectively.

2. GROUND-WATER WITHDRAWAL--Ground-water withdrawal during July through September 1994 has averaged 919,400 gallons per day, while annual withdrawals in 1992 and 1993 averaged 935,900 gallons per day and 953,800 gallons per day, respectively.

3. CHLORIDE CONCENTRATION OF PUMPED GROUND WATER--At the end of September 1994, the chloride concentration of the composite water supply was 56 milligrams per liter, well below the 250 milligrams per liter secondary drinking-water standard established by the U.S. Environmental Protection Agency. Chloride concentrations of the composite water supply from July through September 1994 ranged between 51 and 78 milligrams per liter.

4. CHLORIDE CONCENTRATION OF GROUND WATER IN MONITORING WELLS--Chloride concentration of ground water in monitoring wells at Cantonment and Air Operations increased in July and August, but have leveled off or decreased in September. There has been a general trend of increasing chloride concentrations in the deeper monitoring wells since the 1992 dry season, which began in March 1992.

5. FUEL-DIVERSION PROGRAM AT AIR OPERATIONS--A fuel leak at Air Operations caused the shutdown of ten wells in May 1991. Four of the wells resumed pumping for water-supply purposes in April 1992. The remaining six wells are being used to hydraulically contain and divert fuel migration by recirculating 150,000 gallons of water each day.

**STATUS OF GROUND-WATER RESOURCES AT

SUMMARY OF HYDROLOGIC AND CLIMATIC DATA,  
JANUARY 1992 THROUGH SEPTEMBER 1994**

By Jill D. Torikai

**INTRODUCTION**

Background

Diego Garcia Atoll is a British Indian Ocean Territory and the site of a U.S. Navy Support Facility. The island's drinking-water supply is derived from ground water by a system of more than 100 shallow wells in five production areas (fig. 1). Water from the Cantonment and Air Operations areas combined account for about 99 percent of total island pumpage. The remainder is pumped for local use at Industrial Site South, Transmitter Site, and GEODSS Site. The system has been in operation since 1978 and has provided about 1 Mgal/d since 1984.

Long-term ground-water management is facilitated by a cooperative agreement between the Navy Support Facility and the U.S. Geological Survey (USGS). The Diego Garcia Long-Term Ground-Water Management Program involves data collection and analysis of daily rainfall, daily pumpage for individual wells, and chloride concentrations of water from all production and monitoring wells. The data are stored in a computerized database and analyzed for hydrologic responses to pumping and climatic variability. This report summarizes recent hydrologic events and identifies trends in the data.

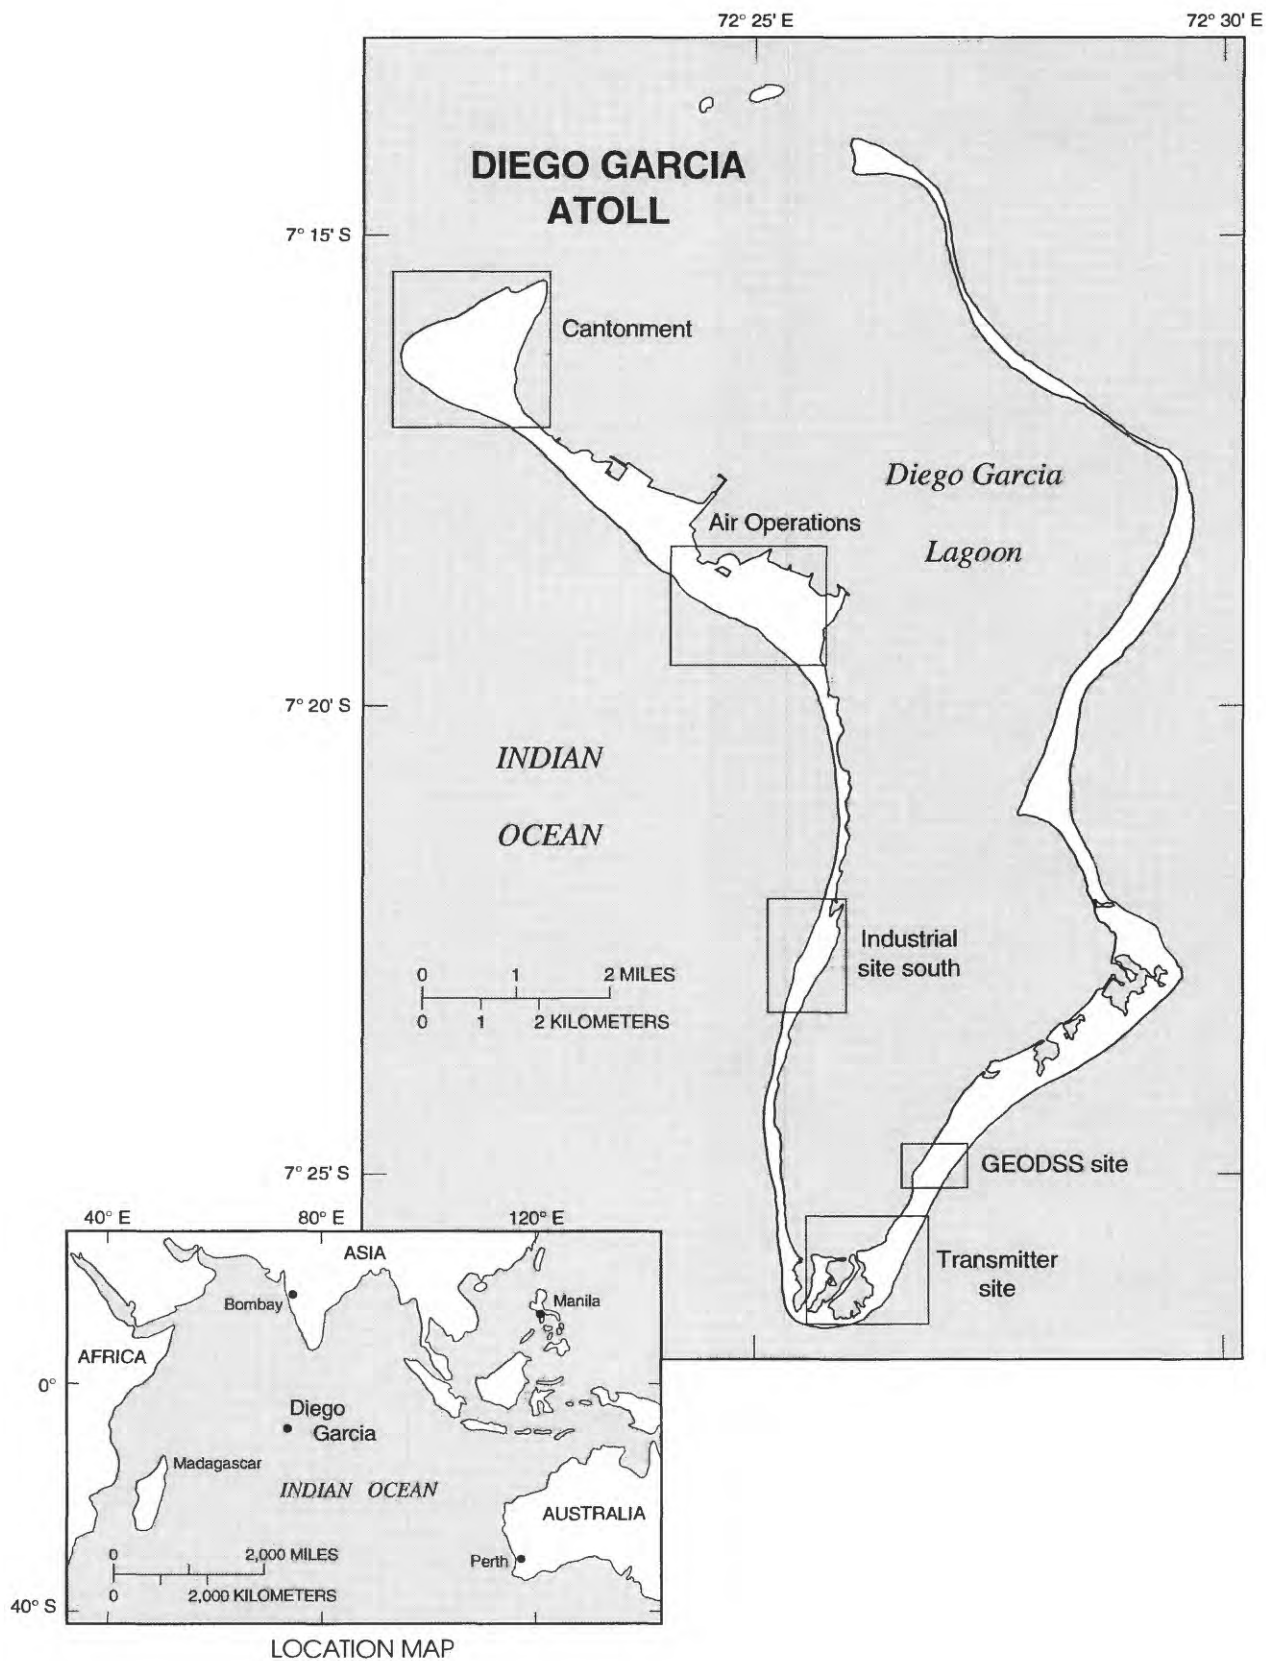

Organization of Report

This data summary contains hydrologic and climatic data that describe the status of ground-water resources at Navy Support Facility, Diego Garcia. Data presented are from January 1992 through September 1994. Data of primary relevance to the water supply are:

1. Rainfall
2. Volume of ground water withdrawn by production wells
3. Chloride concentration of pumped ground water
4. Chloride concentration of ground water sampled from monitoring wells
5. Volume of ground water injected at Air Operations

The following narrative highlights trends in the data for July through September 1994. Ground-water withdrawal and chloride concentrations of water from individual wells are presented in the "Hydrologic-Data Section" at the end of this summary. The data section contains the following:

- A. Maps of production and monitoring wells at Cantonment and Air Operations
- B. Graphs of monthly mean ground-water withdrawal, January 1992 through September 1994
- C. Graphs of weekly chloride concentration of pumped water, January 1992 through September 1994

**Figure 1.** Areas of ground-water production, Diego Garcia.

## RAINFALL

**Background.**--The mean annual rainfall at Diego Garcia for the fixed base period 1951-90 is 105.78 in/yr, with considerable month-to-month and year-to-year variability. A wet season occurs from about September through February, and a dry season occurs from about March through August.

**Recent trends.**--Total rainfall for the first nine months of 1994 was 76.57 inches which is 72 percent of the mean annual of 105.78 inches. At the same time in 1992 and 1993, total rainfall was 67.39 inches and 68.96 inches, respectively. In both those years, total rainfall was below the mean annual rainfall: 92.99 inches or 12 percent below the mean in 1992, and 94.77 inches or 10 percent below the mean in 1993. Low rainfall has been recorded since 1992, but recorded rainfall values have been closer to the means thus far in 1994.

Figure 2 shows graphs of recorded rainfall amounts and rainfall departures from mean monthly rainfall values. Periods of low rainfall can be inferred from the graph when the departure from the mean monthly rainfall is less than zero.

DEPARTURE, IN INCHES

Figure 2. Monthly rainfall and monthly departure from mean monthly rainfall at Air Operations, Diego Garcia, January 1992 through September 1994.

## GROUND-WATER WITHDRAWAL

**Background.**--Withdrawal is measured by flow meters at all production wells and storage tanks in the water system, and is recorded daily. There are 102 production wells that are situated in five ground-water production areas, of which 80 wells are in the Cantonment area. The wells in the Cantonment area are further divided into sub-groups, and the measured ground-water withdrawals are reported as such in this summary.

**Recent trends.**--Figure 3 shows time series of monthly mean withdrawal islandwide and in each ground-water production area from January 1992 through September 1994. Patterns of withdrawal in 1994 have not changed appreciably from prior years in all areas. Total islandwide withdrawal has increased by less than one percent from 953,800 gal/d in 1993 to 956,000 gal/d in 1994, with the Cantonment area supplying most of the extra demand. Pumpage from the Cantonment area has also increased since 1991 because of the May 1991 through April 1992 closure of 10 Air Operations wells due to a fuel leak near those wells. Six Air Operations wells still do not pump to the water supply because of the fuel leak. Ground-water withdrawals from the other ground-water production areas have been held at fairly regular rates since 1992.

Figure 3. Monthly mean ground-water withdrawal islandwide and in the ground-water production areas, Diego Garcia, January 1992 through September 1994.

## CHLORIDE CONCENTRATION OF PUMPED GROUND WATER

**Background.**--The chloride concentration of pumped ground water is used as a quantitative measure of salinity in this summary. Chloride concentration in seawater at Diego Garcia is about 19,500 mg/L whereas a concentration of 250 mg/L is the maximum contaminant level (MCL) under secondary drinking-water standards established by the U.S. Environmental Protection Agency. Secondary standards are not enforceable limits, but instead establish goals for constituents that may affect the aesthetic qualities of drinking water, such as taste or color.

Water is sampled weekly at all wells and storage tanks in the production system. Water in the Air Operations tank is a blend of ground water withdrawn from wells in the Air Operations area only, whereas the Cantonment tank is a mixture of ground water from wells in both the Air Operations and Cantonment areas. This composite tank stores about 99 percent of total island pumpage. Thus, the chloride concentration of water sampled from the Cantonment tank is considered representative of the overall water supply.

**Recent trends.**--The chloride concentration of the composite water supply at the end of September 1994 was 56 mg/L, well below the 250 mg/L secondary drinking water standard. The range of chloride concentrations for the composite water supply ranged from 51 to 78 mg/L during July through September 1994 (fig. 4). Chloride concentrations of the composite water in the Cantonment tank has remained at less than 100 mg/L since 1990 (Torikai, 1995). Chloride concentrations of water sampled from Industrial Site South and Transmitter Site are 100 to 300 mg/L, and is about 100 mg/L at GEODSS Site. Chloride concentrations from these three ground-water production areas commonly fluctuate by about 100 mg/L each month.

Chloride concentrations for Modules A through L at Cantonment (fig. A1) have not been reported since mid-November 1993. Increases in chloride concentration in wells H1 through H7 have been observed during July through September 1994 (see fig. C2 in the Hydrologic-Data Section, p. 36). Wells H4, H6, and H7 have shown increases in chloride concentration since mid-1991 (Torikai, 1995). Wells Q1, Q2, Q4, and Q6 at Cantonment show similar trends (see fig. C3 in the Hydrologic-Data Section, p. 38). Chloride concentrations in wells AO-2 through AO-9 increased in mid-1991, leveled off by late 1991 (Torikai, 1995), and have remained fairly constant through September 1994 (see fig. C4 in the Hydrologic-Data Section, p. 39).

Figure 4 continued.--Weekly chloride concentration of pumped water in the ground-water production areas, Diego Garcia, January 1992 through September 1994. Rainfall data are shown for comparison.

## CHLORIDE CONCENTRATION OF GROUND WATER IN MONITORING WELLS

**Background.**--Ground-water chloride concentration is measured monthly at 35 monitoring-well sites. Each site comprises several wells, with each well having a short screened (open) interval that bottoms at a different depth. The deeper wells typically tap the freshwater-saltwater mixing zone that underlies the freshwater lenses.

**Recent trends.**--Monitoring sites AW16 and BW09 have been selected to show trends in ground-water chloride concentration at Cantonment and Air Operations Areas, respectively. Figures 5 and 6 show time series of chloride concentration at different depths at these sites, with rainfall data included in the figures for climatic reference. Chloride concentrations of the water increased at both sites during July and August, but leveled off or decreased in September 1994. The increases in chloride concentration tend to be larger with increased depth of the well, and appear to lag by one or two months from periods of low rainfall. Chloride concentrations have increased in the deeper monitoring wells since about March 1992.

Figure 5. Monthly chloride concentration of ground water in monitoring wells at site AW16 at Cantonment, Diego Garcia, January 1992 through September 1994. Rainfall data are shown for comparison.

Figure 6. Monthly chloride concentration of ground water in monitoring wells at site BW09 at Air Operations, Diego Garcia, January 1992 through September 1994. Rainfall data are shown for comparison.

## FUEL-DIVERSION PROGRAM AT AIR OPERATIONS

**Background.**--The normal pattern of ground-water withdrawal at Air Operations has been disrupted since May 1991 by a jet-fuel leak at the South Ramp Parking Apron (fig. A2). In April 1992, a program was initiated to hydraulically divert fuel away from the production wells. The fuel-diversion program consists of pumping water from wells AO-14 and AO-15 and directing this water through the common collection main to the wells nearest the leak (AO-10, 11, 12), where it is injected back into the aquifer. Wells AO-10 through AO-15 were shut down from May 1991 to April 1992, but have since been used in the closed recirculation loop of withdrawal and injection.

Injection data for wells AO-10, 11, 12 from May 10, 1993 through September 1994 are actual water-meter readings. From April 1992 through early May 1993, meter readings of injection were not available, and daily injection at each of the three wells was estimated to be one-third of the total daily withdrawal from wells AO-13, 14, 15 which provided the injection-supply water. Monthly mean withdrawal and injection at wells AO-10 through AO-15 are shown in figure 7.

**Recent trends.**--Withdrawal and injection rates for the hydraulic-diversion program are based on target rates for wells AO-10 through AO-15, with total water recirculation of 150,000 gal/d (table 1).

Table 1. Target and actual withdrawal and injection rates for hydraulic-diversion program. [Injection is denoted by negative values; all values are in gallons per day.]

Well	Target rates	Daily mean rates, July through September 1994
AO-10	-30,000	-33,568
AO-11	-50,000	-49,033
AO-12	-70,000	-52,723
AO-13	0	0
AO-14	70,000	64,795
AO-15	80,000	82,929

Figure 7. Monthly mean ground-water withdrawal and injection at wells AO-10 through AO-15 at Air Operations, Diego Garcia, January 1992 through September 1994. Injection is plotted as negative withdrawal.

# HYDROLOGIC-DATA SECTION

## TYPES OF DATA INCLUDED

- A. Maps of production and monitoring wells at Cantonment and Air Operations
- B. Graphs of monthly mean ground-water withdrawal, January 1992 through September 1994
- C. Graphs of weekly chloride concentration of pumped water, January 1992 through September 1994

## DESCRIPTIONS OF PRINCIPAL PRODUCTION SOURCES AT CANTONMENT AND AIR OPERATIONS AREAS

### Cantonment Area

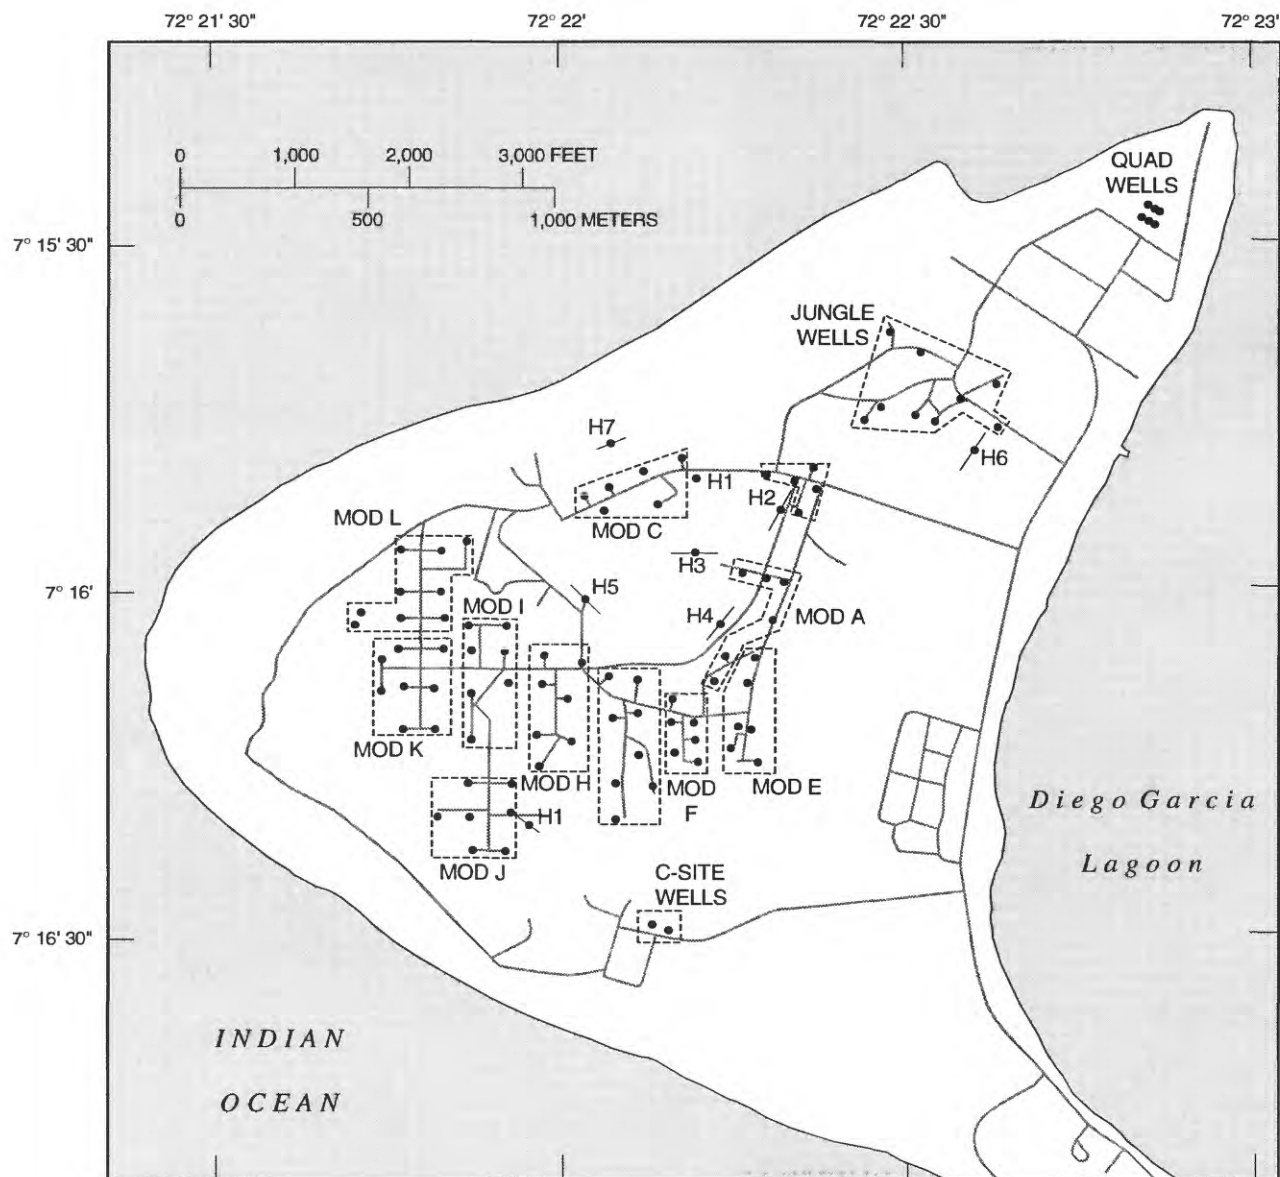

- 1. Modules A, C through L - each module is a well field of 5 to 8 vertical wells that pump to a common collection/transfer tank.
- 2. Module B is a horizontal well with a collection/transfer tank; has not pumped since August 1986.
- 3. Wells H1 through H7 are horizontal wells.
- 4. Quad wells are a well field of four vertical wells.
- 5. Jungle wells are a well field of 11 vertical wells; have not pumped since February 1987.

### Air Operations Area

- 1. Wells AO-2 through AO-5 are vertical wells.
- 2. Wells AO-6 through AO-9 are horizontal wells.
- 3. Wells AO-10 through AO-12 are horizontal wells; currently receiving injection water to divert fuel contaminants from a nearby spill. No samples are currently collected for chloride concentration analysis.
- 4. Wells AO-13 through AO-15 are horizontal wells; AO-14 and AO-15 are currently pumping water to injection wells AO-10 through AO-12, while AO-13 is not pumping.
- 5. AO-16 through AO-19 are horizontal wells.
